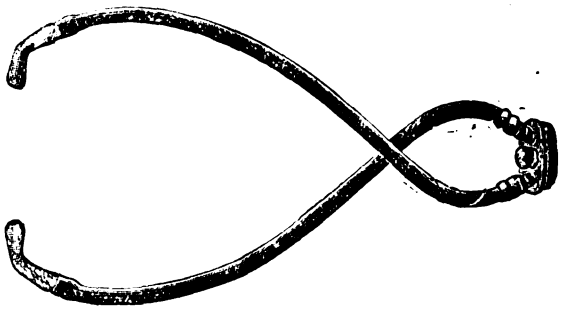
The Royal London Ophthalmic Hospital Reports. Edited by R. MARCUS GUNN, F.R.C.S. Vol. XIII., Part II., December, 1891. London: J. & A. Churchill.—This part bristles with statistics. Messrs. Lawford and Treacher Collins supply notes of 103 cases of sarcoma of the uveal tract. These notes include a large number of published cases, but much trouble has been taken in obtaining information in regard to the subsequent history of the patients, a point often neglected in the original account. Such collections of cases are very useful, and many general conclusions can be drawn from them. Sarcoma of the uveal tract appears to occur with about equal frequency in the two sexes and in the two eyes, males being rather more commonly affected than females, and the left eye more than the right. Of the total number of cases, the after history of seventy-nine has been traced. In twenty cases three or more years have elapsed since the removal of the primary growth, and the patients are still alive. The removal of the growth at as early a period as possible is clearly imperative, as the disease is a progressive one. Mr. T. Holmes Spicer gives an analysis of 158 cases of acute purulent ophthalmia, excluding as a rule those of ophthalmia neonatorum. The great majority of the cases resulted from gonorrhœal infection. The two sexes were equally affected. The results were always worst in patients over thirty years of age. The treatment applied was very various. The importance of Buller's shield and early treatment is strongly dwelt upon. Mr. Nettleship gives some interesting cases of temporary blindness during lactation, and Mr. Treacher Collins supplies two papers—one on the Operative Treatment of Glaucoma, and the other on a case of Tumour in each Orbit.

Digitized by Google

The former is highly instructive, giving an account of the appearances presented at the point where the incision for the iridectomy or sclerotomy had been performed. The paper is illustrated by many coloured cuts, which are reproductions of photo-micrographs, a very creditable piece of work.

The Frog: an Introduction to Anatomy, Histology, and Embryology. By A. MILNES MARSHALL, D.Sc., Professor in the Victoria University. Fourth Edition. Pp. 163. London: Smith, Elder, and Co. Manchester: Cornish. 1891.—This work is divided into nine chapters, each dealing either with one of the systems of the animal, as the nervous, circulatory, muscular, and osseous, or with its histology or development. An introductory section deals with the Processes and Methods in Common Use in Biological Inquiry. There are many illustrations. The dissections are accurate, and the descriptions are given in short paragraphs that are both intelligible and easy to be followed by the student. The careful dissection of one such animal as the frog should be done by every medical student, and would form an excellent introduction to the study of human anatomy.

On the Ambulance Organisation and Medical Arrangements of an English Army Corps in the Field. Together with a Description and Plan of "Bearer Company" Practice as carried out at Netley. By Surgeon-Captain C. J. ADDISON, Army Medical Staff. Netley: J. T. Lemon.—This little book is well described by its title. It is just what it pretends to be, and is written clearly and to the point. Its author is the instructor at Netley in matters of drill to the surgeons on probation, and his method of dealing with the subject is based upon experience. A good deal of information of a precise and useful kind is compressed into a small compass, and the method pursued is plainly and concisely put, and likely to be a great aid to members of the Militia and Volunteer Medical Staff Corps in their various ambulance drills. A short sketch is afforded of the objects, origin, and development of the organisation; and the conditions under which the severely wounded soldier is found after having been struck down in the fighting line are enumerated and practically considered. The plan of "bearer company" practice and of the formation of dressing and collecting stations as carried out at Netley, with the detailed description, make the system quite plain.



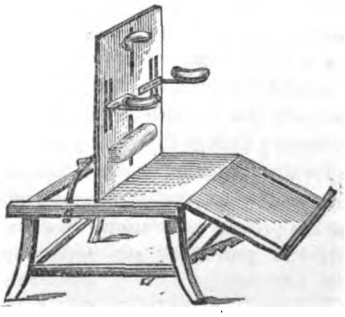
The Strange History of a Dynamo. By T. E. GATEHOUSE. London: H. Alabaster, Gatehouse, and Co.—The objects the author of this *brochure* had in view were: first, to attempt to give in plain language a popular exposition of the dynamo-electric machine, which could be readily understood by the non-technical reader; and secondly, to bring more prominently into publicity the most noteworthy achievements of a devotee of science. The story is told by a dynamo, which is supposed to relate the history of its evolution. Those who wish to know all about the dynamo from its birth and "up to date" will do well to read this interesting and well-written account.

Wilson's Legal Handy Books: the Law of Bankruptcy. By C. E. STEWART, M.A., Barrister-at-Law. London: Effingham Wilson and Co.—This series of little books on legal subjects is well-known, and has no doubt proved to be of great utility to a large circle of readers. The present deals with a large subject, and will fully sustain the reputation of the series. Bristling with technicalities, the topic is not susceptible of simple, barely indeed of intelligible, treatment, and we will not pretend, therefore, that Mr. Stewart has succeeded in producing an attractive book. But technical handbooks are seldom attractive, and on the more appropriate ground of usefulness this latest addition to Mr. Wilson's library of publications need occasion him no misgivings.

New Inventions.

A NEW STETHOSCOPE.

IT was not until I was conversing upon the varieties of stethoscopes with Dr. B. W. Richardson the other day that I realised the value and convenience of one made for me by Messrs. Maw, Son, and Thompson some years since, and which I always use. It is composed of two pieces of india-rubber tubing each two feet two inches long, with vulcanite ear-pieces at the upper ends, and tubes for insertion in the oval chest-piece at the lower extremity, also made of



vulcanite. The chest-piece is seven-eighths of an inch in length and five-eighths of an inch in width, and cupped inside. The instrument can be carried in the waistcoat pocket or most conveniently in a pistol pocket made in the trousers. It is the most sensitive stethoscope of its kind. The tubes are inserted separately into the chest-piece, not terminating together, as in Dr. B. W. Richardson's original pattern. It differs from Stearne's stethoscope by the chest-piece being much smaller, and oval instead of round, allowing it to be applied to the intercostal spaces, frequently detecting mischief not recognisable by means of the ordinary instrument. There is no occasion to lean over the patient under examination or to inhale the patient's breath. The instrument is manufactured by Messrs. John Richardson and Co., Leicester.

JOHN R. PHILPOTS, L.R.C.P. & S. Edin., J.P.
Parkstone, Dorsetshire.

CHAIR FOR SPINAL CURVATURE.

MR. ALFRED CARTER, 47, Holborn Viaduct, has invented a chair for the prevention and treatment of spinal curvature. It is so constructed as to afford support to the spinal column while the patient is in the sitting posture, thus dispensing with the progressive weakness arising from maintaining the prone position for a prolonged length of time.

The illustration given shows the manner of adjusting the crutches to the axillæ and of fixing the pillows in the position required by the patient. The legs can also be supported at any angle, and the whole apparatus can be brought to a horizontal plane and used as a reclining board.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 27, 1892.

UNDER the title "The New University for London," Prof. KARL PEARSON, M.A., of University College, has published a small volume dealing with the history and the defects of the scheme. The history is past, and therefore the larger part of the volume is only of interest to those who have followed the various phases of the movement for the foundation of a "Teaching University" in London from its commencement to its present standpoint. The historical part of the work is simply a reproduction of the letters of Professor KARL PEARSON and other controversialists to the *Academy* and other papers. Some twenty pages deal with the present aspect of the question. Professor KARL PEARSON has come to the conclusion that all that is reasonable in the opposition to the Charter is, that Parliament ought to be induced not to express unqualified disapproval of the Charter, but to petition against its being granted until it is modified by provisions: "(1) For the removal of the religious test; (2) for the ultimate appointment of all teachers by the University itself; (3) for the granting of M.D. degrees only to such persons as shall have gone through the full medical curriculum of the University itself after its establishment; (4) for wider powers of extra-collegiate lecturing." This is the most important assault from the academic side on the proposal to grant the Charter of the new University. There is only one chapter written since the union of the Gresham College with the promoters of the new University has been officially announced, and this chapter is but historical in relation to the past history and suggestive as to the future development of the Gresham College. The various phases of the question from a medical point of view have since 1884 been regularly brought before our readers. It is therefore unnecessary for us to again discuss those points; we will simply deal with the objections which seem to Professor PEARSON sufficient to suggest the emendation of the Charter, but which are not enough in his view to warrant an appeal to Parliament to express unqualified disapproval of it. It is doubtful if Parliament can express a modified disapproval of the scheme. So far as we understand, the Charter must be passed or rejected *en bloc*, and we ask the dissentient professors in Arts and Science at University College to seriously consider whether, if the scheme for the formation of the Gresham University fails, any other and what possible alternative is likely to be carried in the present generation. We will now deal *seriatim* with the provisions set forth by Professor PEARSON.

1. The writer of the article in the *Quarterly Review* for January, 1892, who is by no means friendly to a new University, disposes of the question of the religious test in King's College, as a part of the new University, in the following words: "There is, in fact, no incongruity between a sectarian college and an unsectarian university, or any good reason why the one should not comprise the other as one of its component parts."

2. This means the absorption of the governing bodies of the two Teaching Colleges and the ten medical schools into the Senate of the University. To whom, then, shall be given the power to appoint professors? If the two Teaching Colleges alone were to form a new University this suggestion might be possible, although we do not believe it would ever be carried out; but the inclusion of the medical schools (and a University in London which does not include them is impossible) will obviously render Professor PEARSON'S provision impracticable. The working arrangement favoured by the author in regard to the medical difficulty is that suggested by Professor LANKESTER—viz., the complete divorce of the clinical teaching at the Colleges from the science teaching, the science teaching at the various medical schools to be entrusted to University readers, "who might continue to be, as they now largely are, peripatetic." It is on such impossible lines that an ideal University—that is to say, on the Scotch or German system—should, according to Professor PEARSON, be founded. Anyone familiar with medical education in London will at once see that such an ideal could never be realised. Existing institutions must be federated, and then doubtless a considerable concentration of teaching power will follow. New University lecturers may be appointed under the Gresham Charter, and these will necessarily deal with advanced and special subjects, so as not to clash with the ordinary teaching. Theoretically, undoubtedly, the appointment of professors should be in the hands of the Council, but practically, in the existing circumstances of London, this cannot be done. As the Bishop of London says in his letter published in *The Times* of Wednesday, "A paper constitution is easy to make, and it may be made to fit any theory that you like; it may satisfy ideal conditions; it may be deduced from high philosophical principles; but it almost invariably fails."

3. With regard to medical degrees, we would call Professor PEARSON'S attention to Sir GEORGE YOUNG'S letter in our last issue, in which he disclaims having ever suggested a lowering of the education in Arts and Science, and also to the statement of the delegates of the medical schools of London (p. 495), in which such an intention is expressly repudiated. Even the diplomates of the London medical schools, whilst anxious to have their past curriculum taken into consideration, deprecate in their petition "any modification of the nature or extent of the examinations for the new degree in their especial favour," and it was only to this body that Mr. ERICHSEN'S oft-quoted letter referred, in which he expressly states that his opinion of a clinical examination only was quite unofficial.

4. Extra-collegiate work is specially mentioned in the Charter; but the claim that attendance on "extension" lectures is to entitle a student to graduate is surely extravagant. The aim of collegiate training is to secure a continuous course of study, and this is absolutely impossible under the system of the University Extension Lectures. No certificate of continuous study has yet been gained by any student attending them. They are intended for the masses, and must be more or less popular, and such as

Digitized by Google

require no special preliminary training in those who attend them. We will not reproduce Professor PEARSON'S severe strictures on the graduates of the University of London who are petitioning against the Charter for a Teaching University, but will conclude by saying that his ideal is impracticable in London, and that we fear he is only doing mischief by so strenuously pursuing it and refusing to improve the means at his disposal. His attitude towards the medical aspect of the problem is obviously due to his imperfect appreciation of the magnitude of the problem to be solved and to his ignoring of the possibility of its solution which the Charter of the Gresham University affords. His idea of a medical man's duties and qualifications may be gathered from the following quotation: "Personally regarding ÆSCULAPIUS as a man whose chief function is to cheer us up by bright conversation when in a depressed state of mind, we should prefer to call in an M.D. Cantab., that he might talk 'auld lang syne.'"

THE need for regulating the height of rooms intended for human habitation has long been recognised, and a large number of sanitary authorities have made by-laws on the subject for many years past. But after the issue by the Local Government Board of their Model By-laws in 1877, sanitary authorities desirous of amending their existing codes as to new buildings were refused a by-law on this special question. It was strongly contended by some of them that sanction to such a provision was justified on the ground that it had to do with the ventilation of rooms, and as such was authorised by that portion of Section 157 of the Public Health Act, 1875, which gave to urban sanitary authorities the power to make by-laws "with respect to the ventilation of buildings." The sanitary value of such a regulation was fully admitted, and with the intention of disposing of the doubts entertained as to its legality the opinion of the law officers of the Crown was sought on the point. That opinion, which was signed by Sir HENRY JAMES and Sir FARRER (now Lord) HERSCHELL, was to the effect "that an urban sanitary authority has no general power, under the 157th section of the Public Health Act, 1875, to make by-laws regulating the height of rooms for the purpose of thereby securing improved ventilation. There may, however, be cases where reasonable regulations made with reference to the mode of ventilation would necessitate the rooms being of a certain height." The indirect method of attaining the end in view which the law officers suggested was evidently not found to be a practicable way out of the difficulty, for the result was that no power to regulate the height of habitable rooms has ever been granted under the general statute law.

The defect was fortunately remedied in the Public Health Amendment Act, 1890, Section 23 of which gives the power to make by-laws with respect, amongst other matters, to "the height of rooms intended to be used for human habitation." And the Local Government Board, having apparently found reason to educate sanitary authorities as to what should be regarded as constituting a reasonable height for the purposes of health, have issued a Memorandum on the subject, which has been drawn up by their medical officer, Dr. BUCHANAN, and their architect, Mr. P. GORDON SMITH.

After explaining that, for obvious reasons, the minimum permissible height alone needs regulation, the Memorandum points out that under customary conditions low-pitched rooms are comparatively more difficult to keep fresh—that is, to ventilate—than rooms of a greater height, and that it is essentially in sleeping rooms that the determination of an adequate height is most important, more especially because the occupants are not able during sleep to vary the conditions of air movement through the room. The height of a sleeping room obviously needs to bear some relation to its floor space—that is to say, it should be determined with some reference to the number of beds that can conveniently be placed within it. Whether the number of persons occupying the beds shall have enough breathing space to keep them in health or not is the real question, and this must depend in an important degree upon the height of the room. In numberless cases the builders and the occupants too have regard only to floor area, and when this is excessive in relation to height, the natural tendency is to pack too many people in the breathing space available, and, whilst inconvenience on the floor level itself is avoided, overcrowding really results. But overcrowding of this sort is difficult to deal with as a statutory nuisance, and hence it needs to be prevented by having a reasonable standard minimum height of rooms. Having in view these and other considerations, including a proper regard to economy, the Local Government Board advise sanitary authorities to require a minimum height of nine feet for all rooms to be used for human habitation in which the ceiling is throughout parallel with the floor. And, having given this advice, they make it clear that if this standard is locally deemed to be excessive any reduction that will receive their sanction will not extend to any smaller height than eight feet over the total area of the room.

Such a minimum standard can hardly be regarded as excessive in the case of ordinary rooms. Indeed, such difficulty as arises in this matter is generally limited to rooms which are constructed either partly or wholly within the roof, and which are commonly called "attic rooms." When this class of room is considered it will at once strike an intelligent person that a standard which is deemed requisite in order to secure adequate breathing space on a first or second floor must be equally wanted on a third floor, even if the third floor room be an attic. As a matter of fact it is often more requisite in the attic floor than elsewhere, for servants and others, whose health requirements in this respect are as a rule less thought of than those of any other inmates of the house, are the persons generally relegated to the attic. The minimum of eight feet must therefore be upheld in principle; but, according to the Memorandum, the Local Government Board have evidently been advised to make a reasonable concession to local opinion and to custom by announcing that, as regards attic rooms, they will be prepared to give their sanction to a by-law which shall give a *mean height* of not less than eight feet for the entire room. But to those who are acquainted with sanitary inspection and its results it is well known that one of the greatest evils which has

Digitized by Google

to be contended with in the worst class of houses in some districts is the tendency to crowd the floor area in attics by placing either low beds or mattresses in the angle formed by the floor and the sloping roof. This mischievous practice will have to be met in any by-law on this subject, and it is announced in advance that the central authority will require a minimum height of five feet in attics in addition to the mean height of eight feet. This minimum of five feet also operates usefully in the direction of limiting the amount of floor area that can be occupied by beds, and it indirectly facilitates the attainment of the mean of eight feet.

One very helpful part of this useful Memorandum consists in a series of diagrams showing, in the case of houses having roofs of various constructions, how the minimum of five feet and the mean of eight feet can conveniently be obtained. In one of the attics a horizontal ceiling nine feet in height has to be provided over one-half of the floor area; in a second the horizontal part of the ceiling is shown to be eight feet nine inches high over three-fifths of the floor area; and in a third instance the ceiling is eight feet four inches high over five-sixths of the floor area. Other methods of attaining the same end will doubtless present themselves to the minds of architects and others concerned in the construction of dwelling-houses; but it is to be hoped that, in the interests of public health, no attempts will be made to diminish the minimum standards laid down in the Memorandum, but that, on the contrary, the advice of the officers of the Local Government Board will be taken in adopting as a general rule a minimum height of nine feet as regards all ordinary rooms intended to be used for human habitation.

IN the January number of the *Archives de Physiologie* of Dr. BROWN-SÉQUARD, M. E. GLEY gives an account of experiments made by him to determine the effects of the ablation of the thyroid gland in the dog. Hitherto all who have performed this operation on the dog, cat, and ape have found that the result was almost invariably fatal, and in the few cases where it is reported that life has been preserved M. GLEY considers that the successful issue has been due to the presence of accessory thyroid glands which have acted vicariously, and that when the animals have survived for a considerable time death has been really due to the operation, although the connexion with it has been overlooked. In M. GLEY'S operations, which were all performed under strict antiseptic precautions, primary union of the wound was of general occurrence, though occasionally death supervened too rapidly for union to be effected. The first series of symptoms to which he draws attention, and to which he thinks sufficient attention has not been directed, are those indicating disturbance of the functions of the medulla oblongata, or, as he terms them, "bulbar accidents." These may be observed at a very early period, and consist of vomiting and dysphagia. The efforts to vomit, accompanied by salivation, often precede an attack of convulsions, and last till the animal dies, the matters vomited being bile and mucus. Prof. SCHIFF long ago noticed anorexia as an occasional effect of the operation, having observed it three times in sixty cases. M. GLEY finds that it is less rare than Prof. SCHIFF states, for he finds that nearly all the dogs were indisposed to take food, and that when the refusal was absolute it was a sure sign of a rapidly fatal result. But even when the animal preserves its appetite it experiences great difficulty in taking sufficient nourishment, owing to the incessant spasmodic contractions of the masseter and fibrillar contractions of the muscles of the tongue. Moreover, the dysphagia usually present renders it as difficult for it to swallow liquids as solids; and if perchance some food does gain entrance into the stomach, it is immediately rejected, with an increase of the convulsive movements, the animals ceasing to make any attempt to take food. Vomiting occurs even when food is carefully introduced into the stomach by means of the œsophageal tube. In some instances the animal continues to eat, but the food accumulates in the stomach, the abdomen becomes swollen, and the large intestine fails to discharge its contents. The fæcal evacuations occasionally contain blood. In some instances trophic disturbances appear in the form of excoriations, especially affecting the region of the articulations in the fore and hind limbs. These ulcers sometimes suppurate, and never present the slightest disposition to heal. M. GLEY, like most of the previous observers, has seen muscular paresis and partial paralyses occur usually amongst the earlier symptoms, the extensors in particular being affected; the staggering gait, which is so remarkable in the animals affected, is thus caused. On the other hand, spasms are also of frequent occurrence, which in the first instance affect the masseter and temporal muscles, but soon spread to the muscles of the body generally, and seem to be the result of discharges taking place at tolerably regular intervals. This state lasts for two or three days, when a violent general convulsion may occur, with a tendency to tetanus. At this period the acts of respiration are greatly accelerated, in some cases numbering as many as 220 in the minute, and death often supervenes in one of these convulsions. M. GLEY gives some novel and interesting tracings both of the fibrillar tremblings and of the more violent spasms. Coincidentally with the increased frequency of the respiration the temperature rises, 42°, 43°, and even 43·6° C. (110·4° F.) having been noted within three hours of the operation. In the intervals of the convulsive attacks the temperature has been observed by Dr. UGHETTI to fall as low as 4° C. below the normal, and M. GLEY'S observations generally coincide with those of Dr. UGHETTI, though he has not noticed any case in which the fall was quite so great as this. He thinks these effects are attributable to some direct action exerted on the nervous system. Both in the dog and in the rabbit the urine frequently becomes albuminous. Amongst the pathological phenomena that he has observed may be mentioned various local congestions, especially of the cortical substance of the brain and of the cerebellum, of the liver, kidney, and spleen, whilst the mucous membrane of the stomach often presents hæmorrhagic spots. Death may occur any time between the second and the eleventh day. In one case the animal lived for six months after the operation without apparent ailment, and in another the animal is still alive, but has distaste for food and staggering gait. Although these experiments do not afford any clue to the function of

Digitized by Google

the thyroid gland, it must be admitted that they demonstrate the remarkable influence that the removal of the organ exercises on the nervo-muscular apparatus.

THE annual report of the Medical Defence Union, read at the meeting on Wednesday, shows that the Society continues to enjoy the confidence of the profession. It is a matter of great satisfaction that it should be so. The report shows that those who follow the medical calling are peculiarly liable to need the aid and advice of such a Union. It is, perhaps, remarkable, and altogether creditable, that medical men should not oftener be questioned as to the high tone and character of their work, when we consider the peculiar nature and disadvantages of it. The medical man is called to see human nature at its worst, when it is in a morbid state of peevishness, or excitability, or sensitiveness, sometimes of actual depravity and passion. It is not always possible for him to see his patient in perfect conditions and in the company of intelligent and sensible witnesses. Apart from the cases of morbid feeling or avarice in which claims against medical men often arise there is the large number of charges of malpraxis which it is so easy for ungrateful or unprincipled patients to make, and difficult for practitioners to refute, and the mere repetition of which involves a publicity and a worry that are great evils. The report shows clearly the "difficulties and pitfalls of medical practice" by the fact that with a membership of 1828, and after excluding trivial cases, the Union received 102 applications for assistance, in which the complaint was of material importance and required deliberate handling. A careful perusal of this interesting report convinces us that the membership of the Society should include all the practitioners of the country, seeing that it is the only Society which takes under its protection the good name of its members when that is assailed by malice or by thoughtlessness. Union is strength, especially for defence. Men will hesitate before they bring aspersions against a man when they know that he is backed by his fellows and by a well-ordered and responsible society. The report refers to several instances to show that the breath of slander quickly dies out on the appearance of the Union. In one such case a demand for apology and withdrawal of slander by the honorary secretaries obtained by return of post the following: "I humbly beg to apologise, and I willingly withdraw. Trusting you will forgive me."

There are two or three reasons brought out in the report which justify us in commending this Society to the hearty support of the profession. First, the steady growth of the Union and of its funds. The growth in the number of its members in the last four years is eloquently represented in the following figures—1888, 442; 1889, 834; 1890, 1446; 1891, 1828. Secondly, the Guarantee Fund—which, by the way, has not hitherto had to be drawn on—is increasing, as the following figures show. It was in 1888, £538; 1889, £1249; 1890, £2173; 1891, £2826. It is safe to assume that when a society grows so steadily and withal so largely it is giving its members a decided sense of security.

There are other reasons which lead us to recommend our readers to become members of this Union. One of them is because the whole management shows a great deal of judgment and discretion. Not the least indication of these indispensable qualities lies in the fact that the Union keeps itself strictly, and with determination, to its own business. Its primary business is the personal defence and vindication of its own members when they are unjustly assailed in their professional character or capacity. A few members seem to have expected the Union to defend them in other actions, or actions for common debts; but this would be clearly outside the province and purpose of that body. The Council of the Union, too, set their faces against making them a party in professional and Parliamentary agitations. The modest subscription, while sufficient for their purposes, will not bear any such extension, and all men who value the Union for accepting a function hitherto unprovided for will regard its Council with more respect and confidence for firmly keeping it to its proper work. When we are told that the honorary secretaries, Drs. PHILLIPS and BATEMAN (excluding divisional secretaries' work), have written in 1891 no less than 7231 letters, we can easily see that their energies are already strained to the utmost. All this good work and success might be sacrificed in a few weeks by ill-advised measures. It is gratifying, therefore, to learn that changes in the articles of the constitution have been made which secure a continuity of policy by securing a certain perpetuity of office to a proportion of the Council. It is easy to make ducks and drakes of other men's work achieved by great labour and trouble. This disaster we trust will be averted by the unanimous support of the members to an alteration of the articles, which will secure the continuance in office of those whose experience in such special work has brought the Union to its present satisfactory position.

Annotations.

"Ne quid nimis."

THE REGIUS PROFESSORSHIP OF PHYSIC, CAMBRIDGE.

THE announcement that Dr. Clifford Allbutt had been appointed to succeed the lamented Sir George Paget in the Regius Professorship of Cambridge must have come on many with some surprise. Even the "calm and serene air" of Cambridge may have been slightly ruffled by the news, where more than one physician may have had hopes in connexion with the vacancy. All will admit, however, that the actual appointment made is one that is likely to redound to the credit of the University and to import into the region of Medicine there a certain element of freshness and originality which cannot be too highly rated. Dr. Allbutt is M.A. of Cambridge. He graduated there M.B. in 1860 and M.D. in 1868. He was elected Fellow of the Royal College of Physicians in 1882. Before his acceptance of a Commissionership in Lunacy—which we presume he will now resign—he had acquired a high reputation in Leeds and the neighbouring counties as a physician, and his writings on medical subjects were always received with great interest by the profession. The duties of the professorship are not, we believe, onerous. But they are highly honourable. The Regius Professor is, by virtue of his office, at the head of the medical school. He gives lectures, though not on the Scotch scale. He

Digitized by Google

takes part in the examinations, which are now pretty heavy, and presides at the exercises for M.B. and M.D. The office is thus described in a late Cambridge Calendar: "Founded by Henry the Eighth, 1540. Stipend £40 a year, reduced to £34 18*s.* 0*d.* The appointment by the Queen. A house and premises were left to the professorship by Mr. Crane in 1654. The site being required for the building of the Senate house in 1724, they were exchanged for property in Market-street. The present professor also receives £300 per annum from the University chest in lieu of fees for M.B. and M.D. Acts." There have been seventeen professors since 1554, when the first, J. Blyth, M.D., of King's, was appointed. We congratulate Dr. Allbutt on his appointment, and wish him all pleasure and success in the exercise of the functions of the honourable post.

FOOT-AND-MOUTH DISEASE.

THIS disorder continues to spread, notwithstanding the restrictive measures adopted, and there is much reason to apprehend a greater extension. Since we last commented on it outbreaks have been reported in Sussex, at Hayward's Heath—where a herd of fifty-one cows and forty-two sheep were found to be infected,—so that Kent and Sussex are now invaded; and in the south of London—at Peckham—120 fresh cases have been discovered, which, if the animals are slaughtered, will, it is stated, entail an immediate loss of £2000. The Metropolitan Cattle Market at Islington has been closed, in order to have it thoroughly cleansed and disinfected; and every portable article which might carry infection has been destroyed on the spot. The origin of the disease in this country is still a profound mystery. An official report has been published at Copenhagen by Professor Bang, the Government veterinary surgeon appointed to investigate the health of cattle in the district from which those said to have introduced the plague into this country were drawn. The main conclusions arrived at in this report are that there is no possibility of the contagion having been contracted either at Thisted, whence the cattle came, or on the railway from that place to Esbjerg, where they were embarked; and that the disease was not contracted on board the ship which conveyed the animals to London; but that there is great probability of their having become infected in the Islington Market. In support of the last of these conclusions, Dr. Bang points out that one of the four cattle from Thisted was not attacked by the disease, and that no Danish beast which was sold and removed from the market on Feb. 1st, three days before the outbreak was discovered, was found to have been afterwards affected. This gives support to the doubt we expressed last week as to these cattle being the culprits. At any rate, it is now only too evident that the country has again been invaded by a serious disease, notwithstanding the severe lessons which it had already taught us, and which should have preserved us from another visitation. An opening has been left for its admission, and this fact shows that there has been something wanting in our knowledge of it. Whether this want has been due to negligence, ignorance of its prevalence on the Continent, or of the flimsy nature of the boundary that separates Denmark from Holstein, in which the malady is tolerably general, we do not presume to say. We are now more concerned with the public and private interests that are at stake in the United Kingdom, and the dangers that threaten the health of the people through the prevalance of a virulent and embarrassing disease of this kind. The money loss already incurred must be very heavy; what it may be, if the infection is not quickly stamped out, we have the sad experience of former outbreaks to inform us. It is stated that the Agricultural Department has at the present moment forty inspectors constantly engaged in visiting the 2000 dairies in London, in order to discover promptly any cases of foot-and-mouth disease that may appear. These are, probably, irrespective of the staff belonging to the veterinary section of the Department, who are permanently engaged in the suppression of contagious pleuro-pneumonia in cattle. Two orders have been issued by the Department. One revokes a previous order closing the Islington market when the disease was discovered in it. This order came into effect on the 20th inst. The other order prohibits the movement of cattle, sheep, goats, and swine out of the district comprising the eastern and western divisions of Sussex, and also comprising the boroughs of Brighton, Eastbourne, Hastings, Lewes, and Worthing, and the police district of Hove. It will be seen what a small spark is needed to cause a big conflagration in the matter of contagious diseases, and how a little neglect may breed great mischief.

THE SHOP HOURS' BILL.

THE House of Commons on Wednesday evening was engaged debating Mr. Provand's Shop Hours' Bill, and much of what was said confirms the special report on "Sanitation in the Shop," which we publish in another column (p. 490). The matter will be referred to a Select Committee, so that it is necessary to draw the greatest possible attention to the subject and prevent its being shelved. The division in the House of Commons was, however, significant. In spite of Mr. Matthews' opposition and Mr. Balfour's request that the Bill should be withdrawn, Mr. Provand carried the second reading by 175 votes against 152. This shows a strong disposition on the part of the House to effect some improvement in the hard and unhealthy conditions prevailing among shop assistants. We shall be pleased if our reports on the subject add a fresh impulse to this very necessary reform movement.

URBAN SANITARY AUTHORITIES AND THE FACTORY ACT.

THE Bristol urban sanitary authority have hit upon the very practical expedient of publishing a simple digest of the Factory and Workshop Acts of 1878-91 and allied Acts. This sort of synopsis, when folded, can be easily carried in the pocket for reference, and will save much loss of time involved in the tedious process of reading through the Acts. It is drawn up by the medical officer of health and the borough engineer. It is explained that a workshop differs from a factory, inasmuch as in the former no machinery with motive power, steam, water, &c., is used. Then a domestic workshop differs from an ordinary workshop, because the former is a dwelling-house, in which none but members of the same family work together. It is next shown how in urban sanitary districts out of London powers are transferred to the sanitary authority to inspect both factories and workshops, and prosecute summarily the owners or occupiers of any and all such places where insanitary conditions endanger public health. The sanitary authority is, upon a certificate of the medical officer of health or inspector of nuisances, to serve a written notice on the owner or occupier of the factory or workshop, and if the limewashing, cleansing, and purifying is not carried out as ordered, a fine not exceeding ten shillings per day can be inflicted, and the authority may do the work itself and recover expenses summarily. Each sanitary authority must organise a systematic inspection, and not wait till complaints are received. Should the sanitary authority fail to accomplish these duties—and they extend to the inspection of laundries as well as to all factories and workshops, including those where only adult males are employed—the Secretary of State may send a

Digitized by Google

special inspector down, who will supersede the local sanitary authority, take action, and recover expenses from local rates. The sanitary authority has power to inspect any "house" for nuisances from 9 A.M. to 6 P.M. A "house" means a factory and other building in which persons are employed in any manufacture, trade, or business. Where, in such places, persons of both sexes are employed, separate sanitary accommodation must be provided, and in all workshops a proper supply of water must be secured. Domestic workshops do not come under the sanitary provisions of the Factory Act, but remain under the control of the sanitary authority according to the Public Health Act, 1875. In respect to bakehouses, there is practically no change in the law. The very considerable increase of work and responsibility now thrown on the sanitary authorities is set forth by the figures given in respect to the Bristol urban sanitary authority. This authority finds that no less than 1700 workshops where women and young persons are employed are transferred to its control; but adding to these the "adult male" workshops, there will be an increase of some 2000 to 3000 more. The initial work of ascertaining the areas and cubic spaces in each case will necessitate prolonged and systematic inspection. It has already been decided to appoint one extra inspector, and it is probable that this addition will not suffice. Then there are some 600 to 700 new workshops and factories, one-half of which will come under the provision of the Factory Act with regard to stipulations for the construction of proper means of escape in case of fire. This is to be enforced where more than forty persons are employed, and the construction of the factory was commenced after Jan. 1st, 1892. In those cases the sanitary authority must issue a certificate, and a factory cannot be opened until it has obtained this certificate. All this additional work has not been imposed before it was needed, and the Bristol urban authorities are to be congratulated on their apparent desire to carry out the new law with energy and promptitude.

STRYCHNIA IN SNAKE-BITE.

DR. WOLFGANG HUNT of the Toowoomba Hospital, Queensland, gives an interesting account in the *Australasia Medical Gazette* of a case which had come under his care. The patient was a child aged sixteen months. An elder sister, while playing with her a little way from home, heard her scream, and saw a snake clinging to her hand. Running to the house she quickly fetched her mother and an uncle, who found the child crying and holding the third finger of the left hand, on which was a small punctured wound. The snake was killed as it was making off, and found to be a "death adder." The child was taken to the house, and the end of the finger removed, the stump being sucked and drenched with ammonia and ligatures applied to the arm. She was then brought to Toowoomba for the nearest medical aid, ammonia being applied to the hand meantime. An attempt was made to give stimulants by the mouth, but vomiting immediately followed their administration. On admission to the hospital, three hours after the accident, the child was almost comatose, the body and the extremities cold, pupils dilated and insensitive to light, the pulse rapid and irregular. The child was at once wrapped in hot flannels and heat applied to the limbs, while four minims of liquor strychniæ were administered hypodermically, and a strong faradaic current applied to the nape of the neck and along the spine. Fifteen minutes later another four minims of liquor strychniæ were injected, and almost at once a change began to manifest itself in all the symptoms, and in a short time the child recognised and played with its parents. With the exception of a few slight muscular twitchings recovery was uninterrupted; and the child was discharged the next day in apparently perfect health and none the worse, except for the loss of her finger. The case is very important, especially with reference to the means used for procuring recovery—viz., the hypodermic injection of strychnia, and Dr. Hunt is to be congratulated on his success in this case, as well as in that of another patient whom he mentions as having been admitted in a similar condition after being bitten by a brown snake, and in whom also recovery followed the hypodermic injection of strychnia.

WELLINGTON COLLEGE.

WE are authentically informed that on the 12th inst. three cases of diphtheria occurred among the boys of Wellington College at the Imperial Hotel, Malvern. The boys were at once sent to a house which had been retained as a sanatorium. The cases are stated to be of a mild type, and seem to have been imported from Dulwich, from which place two of the three boys attacked had come a week previously. The other boy attacked slept in the same room. The outbreak may be accounted for in several ways. There is the possibility of some of the bedding used at Wellington College having been overlooked in the destruction and disinfection which took place at the time of the last outbreak, or it may be, as is suggested above, an outbreak from a fresh importation of infection. There is also the possibility of a very long period of incubation—a theory which gains some importance from the fact that another case has occurred in a Wellington boy, who has not yet returned to Malvern after a period of ten weeks, and who has not apparently been subjected to any fresh infection. We are glad to state on good authority that the sufferers are now fairly convalescent, and that no fresh cases have occurred.

BLINDNESS INSURANCE.

A PROSPECTUS has been issued conveying what is apparently at present no more than a bare suggestion of a scheme of insurance against the risk of blindness. There are few mishaps which are intrinsically more fitted to be the subject of a provision in this way, for the comparative infrequency of its occurrence should make the premiums very manageably small; while, on the other hand, the extent of the disaster when blindness does befall an individual is so serious as reasonably to claim the attention of those whose future is in this respect seemingly the best assured. The only objection that occurs to us is that insurance in this piecemeal fashion is both costly and bewildering. It is costly because every several branch demands a separate organisation, with all the attendant expenses; and bewildering because the contingencies against which insurance provision may be made are so multitudinous that no man can be expected to deal separately with them all. The branch now proposed might certainly be with advantage added to some of the subsisting insurance schemes, though we doubt its adequacy to form the exclusive material of a new adventure.

VENTILATION OF THE HOLDS OF SHIPS.

A VERY important question concerning the ventilation of holds in ships has been raised by a letter addressed to the secretary of Lloyd's. This letter is written by Mr. J. Stanley Metcalfe, consulting secretary to the North of England Protecting and Indemnity Association. Formerly the hatches were the only means of ventilation for the holds of ships, and these were only lifted off when the weather was fine and dry. Porous cargo had therefore no opportunity of absorbing moisture from foggy or damp weather. But now there are large cowl ventilators, utilised in all weathers, and which let down on to the cargo any amount of damp air. This is readily absorbed, notably by such substances as jute. On the other hand, the ventilation

Digitized by Google

is not sufficient to dry the cargoes. An experiment to illustrate this fact is suggested. If we place dry tobacco in a jar with a small hole in the lid and expose the jar to humid air the tobacco will become quite damp, and then, even if removed into a dry, warm room, it will remain moist for a long time. Though the small hole, like a cowl on a ship, suffices to let the dampness in, it does not suffice to dry the tobacco. But if we remove the lid of the tobacco jar, or, in the other case, the hatchway of the ship, when the temperature is warm and dry, then the tobacco or the cargo will be in a position to be dried by the evaporation of the moisture. We need hardly point out how injurious to the cargoes and to the health of the persons on board such dampness must be. Where there is a vegetable cargo, such as potatoes, onions, &c., the probabilities are that the damp will cause fermentation, and occasion not merely the destruction of the cargo, but a foulness of atmosphere dangerous to health. This is so much the case that captains sometimes close all the cowl ventilators as soon as they are at sea and away from the control of the port sanitary authorities. Evidently the regulations as to the ventilation of the holds where cargo alone is packed require, in the face of these facts, careful revision.

SIMULTANEOUS LIGATURE OF CAROTID AND SUBCLAVIAN ARTERIES.

ON the 22nd inst. Mr. Mackellar ligatured simultaneously the carotid and subclavian arteries in a case of probable innominate aneurysm at St. Thomas's Hospital. The patient, a man aged thirty-four, a constable of the Metropolitan Police, who had been in earlier years a professional runner and afterwards served in the cavalry, felt the aneurysm a month before he came under treatment in the hospital. A special point in the case is that he has undergone ligature of the superficial femoral artery on each side for popliteal aneurysms. The first operation was performed more than four years ago, the second about two and a half years since, and he carried on his duty as a constable until the appearance of the aneurysm for which he is now under care. Since the ligature of the femorals (also by Mr. Mackellar) he has done work in the mounted branch of the service. It is possible that a fall when on duty in November, when his horse fell with him and injured his chest, has had something to do with the causation of the aneurysm for which the recent operation has been rendered necessary. Up to the present, progress has been most satisfactory, the aneurysmal swelling is diminished in size, and the pulsation is considerably less.

EXPORTATION OF THE RUSSIAN FAMINE FEVER.

IN dealing with the Russian famine, we pointed out the danger which other nations incurred. The famine, we urged, would in all probability engender plague and pestilence in Russia, and it was a question whether these evils may not travel further, and Russia become a centre of contagion that will spread to other parts of Europe or Asia. We did not think this evil prophecy would so soon be realised; yet this very week one of the Cunard steamers, the *Umbria*, has been refused free pratique at the port of New York. There were on board passengers from Russia suffering from the typhus fever that has been raging in so many parts of that country since the more general spread of the famine. The *Umbria* was put into quarantine, much to the inconvenience of all on board, and even the saloon passengers were not allowed to proceed to their destinations. The most severe measures of disinfection have been imposed. As the *Umbria* started from Liverpool the passengers suffering from what seems like the Russian plague-fever must have travelled in England while the contagion was going through the period of incubation, and before any precautions were or could be taken. When we consider that the Russians have no particular knowledge of the dangers of infection, that their education, such as it is, and their laws, do not tend to engender in their minds any sense of the duty they owe to the public in such cases, we may feel wellnigh certain that persons suffering from this highly contagious fever will be smuggled into or through England. While famine, religious and political persecution, drive so many Russians to seek refuge abroad, we must naturally expect that a certain proportion of these refugees will bring disease and the germs of disease with them. Therefore we come back to our original contention that the famine in Russia is not merely a local disaster and a local question. We are all more or less concerned and interested in it, and this not merely from motives of humanity, but because our own security is also at stake.

THE HOSPITAL SATURDAY FUND.

THE meeting of the Hospital Saturday Fund at the Mansion House, under the kind auspices of the Lord Mayor, was a distinct success. The fact that the workshop contributions were less than in the year before by £1300, Mr. Acland, the chairman of the fund, attributed to strikes. The fund having now reached nearly £20,000, it begins to excite the respect of the public, and should stimulate the liberality of working men. It is to the organisation in workshops and to the naturally generous and sympathetic nature of the British workmen that we must look for a sum still more worthy of their class in this great metropolis.

MALE NURSES' MUTUAL BENEFIT ASSOCIATION.

A NURSING agency, formed under the above title, has just commenced operations for the purpose of providing trained and certificated male nurses upon terms which shall secure to the nurses themselves the full benefit of their earnings. The principle of such organisations is one which we cannot but approve, since the existing agencies are unquestionably in many instances conducted in such a way as to leave much to be desired from the point of view of the nurse, the proportion of the nurses' earnings which is absorbed by the mere machinery of the agency being so excessive as to merit the reproach of extravagance. When these deductions go to make a private fortune there is no reason why any tenderness should be manifested towards the system which injures, in the interest of the private adventurer, both the public and the nurse. Where the agency is conducted by a hospital or nursing school the case is in a measure different, for it is undoubtedly convenient to the nurses that they should have the opportunity of defraying in this way the cost of their education, and the public gets the benefit of a guarantee of efficiency endorsed by the Training Institution. Yet even in this connexion the fitting limit of the trainer's lien upon the nurse's earnings is not always observed, and cases of hardship undoubtedly arise even where the desire of those who preside over the administration to deal fairly is open to no doubt whatever. These voluntary associations of nurses for the purpose of minimising agency expenses may therefore be very fitly encouraged in the interest both of the public and of the nurse. If they succeed in maintaining a high standard of efficiency, they will benefit both parties. The benefit to the nurse is obvious. The benefit to the public is no less real, since the cost of the nurse's services is necessarily aggravated by the addition of agency charges which, whether great or small, must, like all other costs of the same kind, be paid by the customer. The public then has a substantial pecuniary interest in arrangements which

Digitized by Google

minimise these additional charges, and place at its disposal the nurse's services at but an inconsiderable cost beyond the nurse's pay. So much—and it is a very substantial advantage—the Nurses' Associations have in their favour; whether they will eventually succeed or not must mainly depend upon their ability to maintain a standard of personal and professional qualification throughout their ranks which will command public confidence and support.

THE REPORT OF LORD WANTAGE'S COMMITTEE.

THE report of Lord Wantage's Committee on the condition of the army has been issued on the eve of our going to press, consequently we can only briefly refer to it at present. The Committee have gone into the whole subject in an exhaustive way, and the report appears to be an able and statesmanlike document. Of course, it is not likely that those who hold extreme views, and who either regard our present military organisation as the best or the worst of all possible systems, will be satisfied. Any way, the committee consider it the only one practicable at the present time. On the subject of "short" or "long" service, they hold that short service is a necessity, and that the matter is not open to argument. The present difficulties are not attributable to the short service *system*, but to the fact that successive Governments since 1872 have never carried out the principles on which it was based when adopted. And they go on to demonstrate how the strain caused by filling up the army in India and abroad has necessarily brought about the present state of things. The Committee recommend various changes of an important character for increasing the Home establishments liable to furnish drafts, and for the improvement of the soldiers' position and comfort. Among other things we are glad to notice that attention is directed to the reduction of the guard duties in London, especially at night, so far as is compatible with the proper performance of functions of State and the military training of the men of the Guards. As we said years ago, we have never been advocates for a "coddling" system for our soldiers; but night duties, especially in our climate in winter, entail a constitutional strain on young men, and are a cause of sickness and inefficiency. The number of sentries in London has always seemed to us unnecessarily large.

"PROPHYLAXIS OF HEREDITARY TUBERCLE."

UNDER the above title an interesting paper is contributed to the *Journal de Médecine de Bordeaux* of Dec. 13th, 1891, by Dr. E. Solles. He describes in detail the various observations he has made on animals. He inoculated guinea-pigs and rabbits with matters obtained from scrofulous children, and the conclusions at which he arrives are as follows:—1. When tubercle is hereditary local tubercular lesions develop a longer or shorter period after birth. As a rule these lesions increase in intensity and extent with the age of the patient, and they become more firmly established as time goes on. They obtain their maximum of frequency in young adult life. In the first few years of life there seems to exist a period, of variable duration, in which the spores of the bacilli, although capable of being stirred into activity, are yet capable of being thrown off, and if this takes place the individual may escape. Dr. Solles elaborately describes it as "la période d'inertie silencieuse de l'ensemencement tuberculeux congénital." 2. This period, during which the spores are inactive, lasts a variable length of time, the period apparently depending upon the number of spores which have accumulated within the fœtus and the ease or the reverse with which they are eliminated from the system. 3. The tubercular material may be got rid of in several ways. The fæces and urine of children, tubercular by heredity, have been proved to be capable of producing tubercle in guinea-pigs. The blood, sweat, saliva, and tears, although there is no reason why they should not be infective, have as yet given negative results. 4. Hereditary tubercle is essentially a "parasitic retention." Those affected may escape from local lesions or not, the number of such local lesions depending, as before said, on the number of spores, the rate at which they develop, and the deficiency of resistance on the part of the host. 5. We cannot yet say with certainty whether tuberculosis kills by the actual damage which the organs undergo and the results of those injuries, or by the toxic action of the ptomaines which are evolved, or by toxic agents not yet determined. 6. The preventive treatment of hereditary tubercle must follow on the lines of nature; it consists in aiding and hastening as far as possible the expulsion of the tubercular germs from the organism—in short, to cause the elimination of the spores before they commenced to develop, and if possible before they have become encapsuled by fibrous tissue. The treatment is based on two lines, eliminative and restorative. 7. In the first years of life the physician is obliged to proceed with caution, and to employ only those means which will not be too great a tax on the little patient, and the treatment should be interrupted occasionally, the intervening periods being regulated by the circumstances of the case. This is particularly to be observed with the expulsive treatment up to the age of puberty. The first measures are to ensure that all the secretory organs are acting freely; repeated purgatives, chosen with regard to the age of the patient, should be administered, and the action of the skin assured by active muscular exercise. Dr. Solles thinks that the portal system contains the largest number of spores, and consequently the functions of the liver should be stimulated. Iodide of potassium seems to have a powerful eliminative action. The skin should be further stimulated by hot baths, and also by sulphur baths, and the natural medicinal waters.

EXTENSION OF THE NOTIFICATION SYSTEM.

A VERY suggestive report has been issued by Dr. Henry Armstrong to the city of Newcastle-upon-Tyne, on the question of extending the system of compulsory notification to measles and to whooping-cough. In opening the subject Dr. Armstrong refers to three diseases as typical maladies which are spread by communication between the sick and the healthy—namely, small-pox, scarlet fever, and typhus fever; and, as regards these, he says that they have all been very remarkably reduced both in number of cases and deaths since their notification came into force. And, then, dealing with the contention that, in view of the magnitude of the existing epidemics of measles and of whooping-cough, the expense of notifying these diseases would be an extravagant one, he states significantly that precisely the same argument could have been advanced in respect of scarlet fever, small-pox, and typhus fever in 1882, and that had this view then influenced the Council the reduction in disease and death which notification has brought about would not have taken place. He also refers to the suggestion which has at times been made, to the effect that since measles must be regarded as effective in the pre-eruptive stage, therefore it is useless to notify its occurrence, by reminding the Council that, even if there be inability to check measles during the first few days of its occurrence, that cannot be accepted as a reason for failing to take every precaution possible by way of preventing its spread during the subsequent three or four weeks, when it must also be regarded as infective from person to person. This question of measles notification is naturally attracting much attention by reason of the exceptionally heavy mortality which it occasions, and,

Digitized by Google

owing to the belief that a substantial amount of the spread is due to the aggregation of children in elementary schools, a means of extension that could doubtless be materially controlled by early notification of its existence in households, especially in the case of a district so admirably circumstanced in the matter of hospital provision as Newcastle is. Indeed, we learn that a pavilion containing thirty-three beds is available for such a purpose. Perhaps the most formidable point to be dealt with as regards measles lies in the age of the sufferers. In the year 1889 measles caused 14,732 deaths in England and Wales. Of these, 3129 took place under one year of age, and 9731 more between the ages of one year and three years of age; that is to say, there were 12,860 out of the total 14,732 who can hardly be regarded as coming within any material control that could be exercised in connexion with school operations, and of whom many might not be easily removed to hospital unless the mothers were also admitted. But the mere fact of there being difficulties in connexion with the subject affords no justification for sitting down with folded hands whilst one of our principal causes of mortality goes on unchecked; and Dr. Armstrong is not likely to propose a definite line of action except on the belief that it is a right one to adopt. We should hail any efforts made by sanitary authorities in this direction.

THE INSPECTORSHIP OF EXAMINATIONS AND THE GENERAL MEDICAL COUNCIL.

THE Executive Committee of the General Medical Council on Monday last appointed Dr. Duffey as Inspector of Examinations under the Act of 1886. There were, we understand, about a dozen candidates. Dr. Duffey is M.D. Dub., L.M. Rotunda Hospital, and F.R.C.P.I., ex-Medical Scholar, and Senior Medical Exhibitioner, Trinity College, Dublin; Physician and Lecturer on Clinical Medicine, City of Dublin Hospital, &c. He is also Examiner in Materia Medica and Pharmacy in the Conjoint Board for Ireland and Professor of Materia Medica and Pharmacy in the Royal College of Surgeons, Ireland. Dr. Duffey's fitness for the post will be generally recognised, though we confess to thinking that it would have been but satisfactory that on this occasion the appointment should have been given to a typically English representative. On the last occasion none of the three inspectors answered to this description. Still they did their work very well. Doubtless it will be so in Dr. Duffey's case, but there is something in the difference of point of view. The appointment is only for one year.

THE CREMATION SOCIETY'S TRANSACTIONS.

THIS year's issue of the Transactions of the Cremation Society contains a variety of details which will repay the attention of its readers. Besides a full statement of the purposes, methods, and constitution of the Society, and a careful *résumé* of the history of cremation in this country, we find in the record of the past year a narrative of comparative success with which cremationists have no great reason to be discontented. It is true that only the small number of ninety-nine bodies have been actually burnt in the Society's furnace at Woking, but this total was in the year preceding represented by fifty-four, and in 1885 by only three. The principle of cremation, moreover, has gained the nearly unanimous approval expressed by a regular vote of the International Congress on Hygiene which met in London last August, while crematoria are either in contemplation or in course of erection in London (Ilford), Manchester, Liverpool, and Darlington. We may mention as of special interest the publication in this treatise of the latest contributions by Sir Henry Thompson and Mr. Seymour Haden to the literature of the subject. The opposite views of these gentlemen are well known, but they are here expressed in specially clear and practical terms. The former, in the course of an able argument, advocates cremation, especially in cases of death from zymotic disease, as being the only method preventive of post-mortem infection, which is at once easy and fully effective. His suggestion that a special official be appointed in each parish for the certification of deaths will be recognised as one of much utility. Finally, there is something to be said for his economic sense which grudges the use of cultivable land for the purpose of burial. Mr. Haden, on the other hand, is no less true to himself in asserting the full efficiency of the earth for the chemical and innocuous conversion of all dead animal matter freely committed to its action. This Sir H. Thompson himself does not deny, provided there be no adjacent and contaminable water-supply. A demand for legislative action to enforce the methods of sanitary burial forms a natural part of the earth-to-earth system, and on this point we are entirely in accord with its well-known promoter. Until such action is assured we cannot, indeed, be said to have really tested the efficiency of our burial system; nor would we feel disposed, while it is in abeyance, to prefer, though we may agree to sanction, the much more rapid, though perhaps not otherwise more perfect, process of cremation. The value of the Transactions to students of the new method is enhanced by sectional illustrations of the improved Gorini's furnace used at the Woking crematorium, and by a list of works on cremation available for reference.

THE SPREAD OF SMALL-POX.

THE *Echo* quotes the Consular Report for 1890 on the trade of Philadelphia for the following fact. An immigrant landed in 1872 with incipient small-pox. The city was previously absolutely free of the disease. He escaped medical examination, and moved about from district to district. His trail was followed by the march of the disease. Eventually all trace of him was lost, but no fewer than 2585 deaths from small-pox resulted from his visit to Philadelphia. It is not pleasant to think what similar experiences may be in store in England. The disease is in abeyance, though there are signs of reviving activity. It can be kept in check by sanitary police. But what if one or two cases elude such precautions?

SOCIAL REFORM IN INDIA.

THIS question has been discussed in so many forms and from so many different standpoints that it is hardly surprising to see issued still another contribution to the literature of Indian social reform. Perhaps the glaring need for reform is the explanation. Mr. F. Pincott, well known in connexion with Indian subjects, while approving of the principle, writes in strong disapproval of the age limit of Indian marriage, the severity of the punishment decreed, and of the hasty manner in which the Indian Age of Consent Act was passed. He bases his argument on the inherent difference of customs in England and in India, insists that the passing of the Age of Consent Act fixes the English arithmetical idea of morality on the people of India, and alleges that Indian institutions contain safeguards to obviate the evils which might be apprehended to arise from them. In his view much harm has been done by recent legislation, although to our mind the assertion has still to be supported by proofs. He candidly states that hitherto he has stood alone among Englishmen in his views on this question, and we are inclined to think that the present pamphlet will not materially increase the numbers who sympathise with his view. The author admits that social customs are matters of convenience. It plainly follows that if these customs, social or otherwise, are inherently wrong, a remedy must be found. Custom or

Digitized by Google

habit occurring in individuals or in nations cannot be accepted as a justifiable excuse for disgraceful acts. The South Sea Islander might plead custom in support of his cannibalism. The pretext of obnoxious customs being safeguarded is as thin as the paper bag which encloses a dangerous quantity of gunpowder. On physiological grounds wrong clearly exists. The Hindoo, in this respect at least, does not very greatly differ from the European; and while physiological fact remains a constant factor of the problem it is idle to plead custom, even though safeguarded to an extent far beyond that which is alleged. Mr. Pincott somewhat ingeniously suggests the adoption of a kind of age sliding scale, by which, as he thinks, nature will adapt herself with unerring flexibility to each individual person. A scale of that kind could only result in obviating any beneficial legislation which is likely to be promoted on this subject.

A CASE OF THORACIC ANEURYSM.

IT is matter of common experience that an aneurysm of the thoracic aorta, if it does not implicate any important organs, may attain to considerable size before its presence is revealed either to the patient or to his medical attendant. In not a few cases—especially of aneurysm of the descending aorta—the fatal event has happened without any diagnosis having been arrived at, or even without any notable discomfort having been experienced by the patient. At the meeting of the Berlin Medical Society held on the 3rd inst. (*Deutsche Med. Woch.*, No. 6), Dr. Litten showed a patient forty years of age, who, up to within three weeks of that date, had been working as usual at a factory without any difficulty, although for a twelvemonth he had been complaining of "rheumatism" in the left shoulder. Yet there was obvious bulging in the front of the left side of the chest, most marked in the third intercostal space, where and in the interspace above there was definite pulsation and plain conduction of the cardiac sounds. The heart's apex beat was in the usual place, and, although there was evidence of aortic regurgitation, there was no indication of hypertrophy of the left ventricle. The aneurysmal tumour was distinctly expansile and fluctuating; it probably sprang from the aorta below the origin of the left subclavian artery, and had eroded part of the ribs. There was no difference between the two radial pulses and no delay in the femoral pulses. The left pupil was notably smaller than the right. The patient several years before had a chancre, but it was not succeeded by any secondary signs of syphilis. Dr. Litten commented on the case as showing how large a size an aneurysm in this situation may attain without any distinctive signs being manifest, and he pointed out its further peculiarities in the absence of cardiac hypertrophy in spite of the aortic insufficiency, and also the absence of any delay in the pulse in the lower limbs in spite of the obviously very great dilatation of the descending aorta.

CONTAGIOUS DISEASES ACTS IN TALY.

BY special enactment on March 29th, 1888, the surveillance of prostitution throughout the Italian peninsula was relaxed, and as a consequence venereal disease in its worst forms, particularly at seaports and in garrison towns, so increased that the Government have had to rescind the enactment referred to and return to the regulations previously in force. Professor Angelo Scarenzio, who holds the chair of dermo-syphilography in the University of Pavia, has just read a painfully instructive report on the matter before the Lombard Institute, based on statistics compiled from the various centres of Italian population during the last three years. The aggravation of the diseases in question, not only as to number, but as to virulence, has reached, he says, the point of a *pubblica calamità*. The patients, almost all males, in the institution under his own eye—the "Dispensario Celtico" of Pavia—rose from 166 in the first year of relaxed surveillance to 203 in the second and to 303 in the third; and what impressed him even more painfully was the fact that the augmentation revealed itself especially in the *forme infettanti* (infective forms), which impregnate the system as a whole, and transmit the virus through the medium of generation. In comparison with the other venereal forms, the mean percentage of the infective cases was, he says, in the first year 9·2, in the second year it rose to 17·7, and in the third to 18. Again, in the Foundling Hospital the cases of congenital syphilis, fluctuating between 4·09 and 3·82 in 1888–89, mounted rapidly to 5·22 in 1890 and to 5·46 in the first half year of 1891. The lamentable diffusion of the virus, Dr. Scarenzio adds, is not limited to the classes that have recourse to the "Dispensario Celtico," but it extends to the well-to-do (*ai benestanti*), including special bodies, such as the army and navy. The Government, unable to ignore the facts, have had, by a new regulation issued on Oct. 27th last, to re-establish the obligatory inspection of prostitutes, whether in houses or dwelling apart; to submit the choice of the inspecting physicians to the approval of the Provincial Sanitary Council; to make subjection to treatment compulsory on the patients where there is no guarantee that they can be properly attended to in their homes; and to multiply as well as to maintain the "Dispensarii Celtici." In conclusion, Dr. Scarenzio desiderates "a more vigilant and more extended surveillance, so as to include clandestine prostitution, and bring not only unfortunate women but all venereal patients of the other sex under hospital care." He sees "no reason why the destructive contagion of syphilis should, in comparison with other contagions, be vouchsafed a milder, not to say a favoured, treatment at the hands of the law." This, of course, is but an academic, a pious aspiration, possible of effective fulfilment only in despotically governed States. At the same time one can hardly wonder at its being entertained in view of the horrible statistics that reach us from garrison towns like Ravenna, where the disease is verily a "public calamity," or from seaports like Naples, where Dr. Achille Titomanlio, of the local "Brefotrofio," presents us with such a gloomy picture of the increase of congenital syphilis.

LIFE ASSURANCE CERTIFICATES OF DEATH.

IT is a hard case when a medical practitioner finds himself under the necessity of tilting at the profession to which he belongs, and particularly so when he finds himself called upon to confide his grievances to the lay press; and we are glad therefore to observe that a "Doctor of Medicine," who has recently been writing to *The Times* in a sense which reflects most seriously upon the good faith of his professional brethren, appears to be the victim of a life assurance craze. It is quite obvious, even to the meanest understanding, that the practice of insuring the lives of one's neighbours opens a door to crime. So far the relation thus established does not differ from other human relations, for even those that are most intimate and most benignant are constantly abused by ill-disposed and criminal persons. But from time to time the note of alarm is heard—now from the jury-box, now from the Bench, and again in the correspondence columns of the newspapers—that unsuspecting men, women, and children are being done to death for the sake of the proceeds of insurances upon their lives. It fortunately happens that this particular form of crime cannot become rampant without victimising the insurance offices, an interest that is too active and too vigilant to be easily plundered on any considerable scale. Thus it has happened that, although

Digitized by Google

atrocious crimes have from time to time been brought to light and outraged the public mind, they have invariably proved upon inquiry to be isolated facts, giving evidence, not of a vicious system or a corrupt community, but of the presence of individuals of deep and exceptional criminality. If there be any substance in the charges, which a "Doctor of Medicine" has sown broadcast, of false certificates of death, we are convinced that it comprises only some exceptional facts which have chanced to come under his observation; but so long as such serious allegations rest on the judgment and sound sense of an anonymous correspondent, the profession of medicine may rest content to regard them as a work of imagination somewhat wanting in the power of affording amusement.

WARMING RAILWAY CARRIAGES.

THE Midland Railway Company have long been forward in attention to the comfort and convenience of their passengers. Their initiative has had much to do with modern improvements in third-class accommodation. It was they who first familiarised the public of this country with the railway carriage lavatory. Quite recently their characteristic zeal for any change that tends to increase the amenities of travel has introduced what promises to prove a useful and economical method of carriage warming. In so doing the company have utilised the suggestion of Herr Pfuetzner, mentioned in THE LANCET of May 2nd, 1891. Since the new year trains have been running between St. Pancras and Bradford in which a system of heating by means of pipes in direct communication with the engine has been carried out, so far with complete success. According to this arrangement the pipes can be filled either with steam or with hot water. A moderate average temperature can thus be maintained without trouble. When we contrast this apparently easy and obviously convenient process with the elementary and laborious method until now in common use, and remember that it has been employed in domestic heating for many years past, we can only feel the more surprised that it has not sooner been applied to the purpose above mentioned. It is to be hoped that we shall, as time goes on, have such confirmation of its successful use as will ensure its general adoption by railway authorities. The advantage obviously resulting to the health as well as the comfort of travellers from the assured maintenance of an equable temperature in each carriage need not be insisted on.

DANGERS OF SULPHONAL.

THAT this now much-used drug is not entirely without danger even in medicinal doses has been several times already pointed out, and Dr. John Grant, of the United States Army, has in a recent contribution to the *Boston Medical and Surgical Journal* given two instances of inconvenient and somewhat alarming symptoms arising in patients to whom only twenty grains had been administered. The first patient was a married lady suffering from an attack of influenza, with symptoms predominating in the thoracic viscera and in the nervous system, but who, after a week's illness, considered herself convalescent. As she was still sleepless, twenty grains of sulphonal were given in hot water. In a few minutes profuse perspiration followed, and the patient sank into what appeared to be a sound sleep. Next morning, however, she awoke unrefreshed and in a state of complete prostration, so as to be unable to turn in bed without help. She also had a feeling of severe constriction of the head. On account of muscular weakness the patient was unable for some days to leave her room, but ultimately recovered. The second patient was also convalescent from influenza, but suffered from slight excitement and sleeplessness. Twenty grains of sulphonal were administered at bedtime, with the same almost immediate effect. Next morning he was in a condition of similar prostration, almost unable to move a limb, and suffering severely from a feeling of constriction in the head, and with a weak, compressible pulse. These two cases would seem to show that sulphonal is not without the risk of some inconvenience if administered in cases attended with considerable physical prostration.

DIPHTHERIA AT MONMOUTH.

DIPHTHERIA has broken out in two schools at Monmouth under circumstances which cause a good deal of local anxiety. Perusal of an account of the measures which are being taken lead to the idea that every effort will be made to ascertain whether the disease has been associated with any sanitary defects in the two establishments in question, and if so, to remedy the points needing amendment. This is as it should be. But we have come to learn within recent years that, quite apart from sanitary defects, so-called, there are special conditions attaching to what has been aptly termed "school influence," both in the development and in the spread of this disease, and it is to be hoped these will not be lost sight of. In the meantime, it must be admitted that Monmouth town is, both topographically and sanitarily, a locality by no means favourable to immediate prevention of diphtheria extension. It is, indeed, precisely the sort of town where the disease may be expected to cause difficulty, and to be maintained by a series of sore-throats which at this time of the year often have a tendency for a time to lose the special features which commonly attach to recognised diphtheria.

THE TOXTETH INFIRMARY.

THE Toxteth board of guardians have now decided to provide infirmary accommodation on a reduced scale. Instead of arranging for 420 beds, as originally intended, the scheme adopted relates to the provision of 244 beds, and it is reckoned that the cost will be £32,700. This will, it is estimated, involve a rate equal to one penny in the pound for thirty years. We are glad that the matter is no longer to be postponed.

PANIC AND ACCIDENT.

REGRETTABLE as it is in every way, the recent serious accident at a children's entertainment in the rooms of the South St. Pancras Unionist Club was, in its origin, so simple—we might almost say so natural—that it is difficult to lay down any rule which could be relied upon to prevent its recurrence. A boy jumps up, as restless urchins will, and overturns the lamp of a magic lantern. Some oil escapes and burns upon the floor; no one is burnt, there is little or no danger; but soon there comes the almost inevitable explosion among the nervous elements present in the audience. Some one cries "Fire!" a rush of children follows, and several are dangerously injured. Experience may register more than one lesson in connexion with this incident. Thus we recognise an error, slight, perhaps, in everything but its mischievous influence, in allowing a child to sit anywhere near the lantern; yet who would have thought that this so greatly mattered? Then we have to note and to take account of that unstable nervous temperament, the ground in which all panics grow and which was here so unhappily manifest. Time will be old and education also, we fear, before its cure or disappearance may be looked for; but this is no reason why we should not begin early to teach, as the first principle of safety in the presence of danger, the duty of keeping quiet. First a moment of cool reflection, then action. The lesson must be learned in daily tasks and duties if it is to guide us in a crisis. In a word, it is the common sense of in-

Digitized by Google

dividuals rather than set rules that we must rely upon to prevent such accidents as that above mentioned. Managers of entertainments, it is to be hoped, will also be careful in future, by means of suitable barriers, to keep their audience, adult or juvenile, well away from all apparatus. We need hardly mention the necessity of selecting such managers from among persons of adequate nerve and intelligence. In the case already quoted it is, at least, a matter for satisfaction that they seem to have justified the wisdom of their selection by their cool and rational behaviour.

GRANT COLLEGE MEDICAL SOCIETY.

IN the form of a retrospective address, we have received a clear and interesting account of good work done for medical science and practice by the Grant College Medical Society of Bombay. It is satisfactory to note that the author, Dr. Rustomjee Naservanjee Khory, who is president for the present session, can well appreciate the social and professional advantages of which he is in his official position the visible representative. There is in Bombay (and doubtless elsewhere in India), he reminds us, an undesirable hiatus between the private practitioner commonly of Indian extraction and his hospital *confrère*, who is usually a European. This gulf the influence of the common Society tends to obliterate, and the brief reports of its proceedings given in this address exhibit in rational harmony the fruitful effects of labour done by both classes of workers in the wide field of medical practice. The Society, notwithstanding its efforts and its excellent purpose, does not entirely escape the tribulations which more or less beset all other like associations. We are told that there is room for improvement in its financial condition, and the attendance is not always what it might be. Nevertheless the membership shows a very substantial increase, and much of the material contributed towards its discussions is of high quality. We may therefore fairly expect for it a useful and an enduring future. The presidential address, however, is not occupied solely with a consideration of the Society's affairs. It contains also a short discussion of the pathology of leprosy in relation to its contagious property; and in the same connexion it exposes and explodes an anti-vaccination fallacy of recent growth, which, with hardly a pretence of proof, and in the face of contradictory evidence, maintains that the operation has assisted the spread of that disease. The author strongly advocates the extension of compulsory vaccination, now for more than twelve years in successful operation in the town of Bombay, to other parts of India. His careful paper closes with an appreciative reference to the Hyderabad Chloroform Commission.

INSANITARY DWELLINGS AT PLYMOUTH.

THE powers given to magistrates under the recent Public Health Act are beginning to be felt in districts beyond as well as in the metropolis. The Act gives the magistrates the power to order the closing of the dwellings proved to be unfit for habitation, and to recover from the owner of the property the expenses of removing the tenants. Two tenements, the owner of which was indicted before the borough magistrates of Plymouth on the 11th inst. under this Act, were described as quite undrained, all the closets wall-locked, the floors rotten and saturated, the walls damp and daubed, the roof gaping, and the place utterly unfit for human beings to live in. To add to the deplorable nature of the dwellings, a pony was kept in a cellar on the premises, the floor of its stable being covered with liquid manure. There were twelve rooms in the house, which, however, were not all tenanted, but the building was occupied by six families, mostly in one room each. The excuse urged for this state of affairs was the old one: that the health officer's statements were exaggerated; that there had not been any outbreak of disease; and that therefore there was no proof that the property was insanitary. The magistrates took the wise step of visiting the property and seeing for themselves, and from their own observations they stated that "they could hardly conceive that such a state of things existed in inhabited dwellings. After visiting the houses they could only say that the description given by the witnesses did not adequately represent the actual state of the place." One of the magistrates remarked that it was most painful to him to find people dwelling in such dens in a town surrounded by such natural beauties. By such enlightened action as that of the Plymouth Borough magistrates, who in this case ordered the "dens" to be closed and imposed a penalty of £10 and costs for each of the two tenements, it is certain that in the future, whether near or remote, better sanitary surroundings will be secured, leading to the general improvement of the people.

FOREIGN UNIVERSITY INTELLIGENCE.

Bordeaux.—Professor Pitres has been appointed Dean.

Santiago. — Dr. A. Limonena y Zamalegui has been appointed Professor of Clinical Medicine.

Valladolid.—Dr. A. A. Cortes, Professor of General Pathology, has been appointed to the chair of Medical Pathology. Dr. Luis Roa y Vilchof, Professor of Therapeutics in Grenada, has been appointed to the chair of Hygiene.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Heinrich Rosenthal, editor of the *Allgemeine Medicinische Central-Zeitung*, after only two days' illness.—Dr. Isidor Ganz, the Nestor of Carlsbad physicians, at the age of eighty-seven.—Dr. R. Ritter von Schmerling, body physician to the Grand Duke Albrecht, at the age of eighty-two.—Dr. Hermann Aubert, Professor of Physiology at Rostock.—Dr. R. Brossard, formerly Professor of Internal Pathology at Poitiers.—Dr. Joh. Wagner, Professor of Anatomy at Kharkoff.—Dr. D. Ayers, Emeritus Professor of Surgical Pathology at Long Island College Hospital, Brooklyn.

THE *London Gazette* announces that the Queen has been pleased to direct Letters Patent to be passed under the Great Seal of the United Kingdom of Great Britain and Ireland, granting the dignity of a Baron of the said United Kingdom unto Sir William Thomson, Knt., President of the Royal Society, and the heirs male of his body lawfully begotten, by the name, style, and title of Baron Kelvin of Largs, in the county of Ayr.

WE regret to hear of the death of Mr. George Pearce, who had held the post of divisional surgeon of the B Division of the Metropolitan Police for the last forty-six years. The death of his wife the day before appears to have produced the attack of angina pectoris from which he died on Monday last.

SMALL-POX is said to be raging violently at Saratoff, in Russia, in which country vaccination is not compulsory. In one large village alone 400 children are reported to have died within the last ten days.

THE next International Congress on the subject of the abuse of alcoholic liquors will be held at the Hague in September next.

THE Senatus of the University of St. Andrews has resolved to confer the honorary degree of Doctor of Laws upon Professor Michael Foster, M.D., of Cambridge, and Professor George M'Leod, M.D., of Glasgow.

THE Duke of Edinburgh has appointed Mr. William Hickman, M.B., F.R.C.S., to be Surgeon in Ordinary to his Royal Highness, in the room of the late Sir Oscar Clayton.

DR. F. J. PAYNE has been appointed Joint Lecturer on Medicine at St. Thomas's Hospital.

REPORT OF

The Lancet Sanitary Commission

ON

SANITATION IN THE SHOP.

PART I.

IN these days of labour agitations and of legislation for the protection of labour it is surprising that so little has been done for a large class of workers with whom the public come in daily contact. The victims, for instance, of the East-end sweater, though out of sight and ignored by the public at large, have been discovered and their grievances disclosed; but the shop assistant, who is before us at every turn and in every street, remains unthought of and uncared for. Perhaps it is because he is fairly well dressed and puts on a smile to greet his customers that the public conclude he must be pretty well situated and comfortable. There never was a greater mistake. Even the docker, over whom so much sympathy was expended, is in some respects better off than the shop assistant. Quite a chorus of shop assistants exclaimed in our presence that they wished they could get "the docker's tanner." The Blue-book report on the Shop Hours' Regulation Bill establishes that shop assistants are generally worked eighty-five hours a week, and this at 6*d.* an hour would equal £2 2*s.* 6*d.* a week, but they rarely receive anything like so large a salary. The mechanic as a rule works from forty-eight to fifty-four hours a week, earns 8*d.* and upwards an hour, and need not keep up appearances. The shop assistant works from seventy to ninety hours a week, and competent men earn from 2*d.* to 6*d.* an hour, while there are young persons who do not make more than one halfpenny an hour, yet with this inferior pay they must dress well. What, then, remains in time and in money to procure wholesome relaxation, a healthy home, and sufficient food? The workman is protected by the Factory Act and the Sanitary Act; the shop assistant does not profit by either the one or the other. The Sanitary Act should be of service, but how many sanitary inspectors are there who ever think of examining the premises of retail dealers? For the workmen there are model artisans' dwellings, where the death-rate is below the average death-rate of the metropolis; for the labourer, for the beggar in the streets, there are model common lodging-houses. The homes of the poor are reached by a great variety of agencies. There are missionaries of all creeds, there are official and amateur sanitary inspectors, and any number of philanthropists, who from one motive or another visit slums and the homes of the working classes; but who ever thinks of trying to penetrate behind the scenes of a retail shop, and inspect the rooms where the assistants sleep or have their meals?

The difference between shop assistants and artisans may be noted with great facility in the boot trade. In this trade it often happens that workmen and shop assistants are employed on the same premises by the same master. For instance, we have the branch establishment of a well-known and popular bootmaker. The shop assistants are in attendance thirteen hours and a half for five days a week, and fifteen hours and a half on Saturday. Behind the retail shop there is a workshop, and here the workmen, who are engaged by the week, work ten and a half hours a day, and those who work by the piece nine hours. The assistants in the retail shop profit by the fact that, as the workshop is open to inspection, proper sanitary accommodation has been provided. But the workshop is closed at 6.30 P.M. Then there is no urinal or closet for the shop assistants. What is necessary for the workmen is supplied, but no such care is displayed on behalf of the shop assistants. There are, we are assured, thousands of small shops in London where no sanitary accommodation whatever is provided for the assistants. That, in the absence of sanitary inspection, such should be the case will be readily understood. Many small shopkeepers live on the premises, the closet is upstairs, and is kept locked for the use of the family. A man engaged in a clothier's establishment in the south of London complained that, though there were six assistants in this shop, there was no closet, nor was it possible to obtain a glass of water. There was the bare shop; all that belonged to the house as a dwelling was locked up and reserved for the shopkeeper and his family. As a result, the shop assistants have to run out to the nearest public-house, where they can find a closet and urinal, but where they are compelled to spend a portion of their slender wages in beer. If they are thirsty they have no means of drinking water, and must again resort to beer. Another shop assistant, also working for a clothier, whose shop is situated in the east-end complained that the only cistern available had not been cleaned for several years; the water, therefore, was too dirty to drink. A third shop assistant explained to us that the water in his shop was absolutely foul. It will be readily understood that, what with the flare of gas, the dust, the constant talking to customers, considerable thirst must be experienced, especially in summer weather; and if there is not an abundant supply of pure water on the premises the shop assistants are driven by the force of circumstances to the public-house, and soon find themselves on the high road leading to intemperance. The advocates of temperance would do well to look to this cause of inebriety. There is a philanthropic society which constructs troughs and supplies drinking water to dogs and horses in the street. If the temperance organisations could form a special service to see that a suitable supply of pure drinking water was provided to the human beings who spend the better part of their lives in shops, one of the causes of drunkenness would be removed.

Of course it is only the very small shops that are so badly provided in respect to closets and to drinking water; but, even in large establishments, the accommodation for meals is often altogether disgraceful. At one large grocery shop the assistants complained to us that they were made to take their meals in a dark basement below the level of the street. Here was situated an unventilated closet, with no light and no window. The odour of drains pervaded the whole place. While some grocers allow their assistants to eat their meals near unventilated drains, others do not hesitate to store their provisions round and about closets. This is particularly dangerous when such substances as butter are exposed to the escape of sewer air. At one large provision store, which has branch establishments in different parts of the town, the assistants were loud in their complaints. At one of the branch establishments there was no closet at all for three months. The assistants were obliged to go round to a neighbouring coffee shop. At last they refused to work any longer under such conditions, and then a closet was built for them. At another branch, in the far east of London, the drains were the cause of such an intolerable nuisance, that a plumber was called in and an estimate made for repairs. When, however, the drains were dug up it was found that the extent of the mischief was so great that it was impossible to put them in order for the sum proposed to be expended. The drains were consequently merely covered over again and things allowed to go on much as they were before. It is in the midst of such insanitary surroundings, somewhere in the basement or at the back, that shop assistants are often compelled to take their meals. In the smaller shops they do not have even this much accommodation granted them. We know a high-class dispensing chemist in the West-end where there is neither dining-room nor dispensing-room for the assistants. The dispensing is done behind a screen at the end of the shop, and here, on the dispensing table in the midst of drugs and half finished pills, the assistants have to take their meals.

Digitized by Google

Another shop assistant, who was evidently in a very bad state of health, complained to us that, though his employer spent his Sundays preaching the gospel, he made his assistants work from 7.30 A.M. till 10 P.M. the first five days of the week and till midnight on Saturdays. When this assistant's mother was dying his employer would not grant him a few hours' leave of absence. This unfortunate man, who is kept at work eighty-nine hours a week, is not even allowed to leave the shop for his meals, nor has he a regular hour for meals, but must snatch his food how and best he can in a dirty corner behind the counter.

In some establishments the food is good, ample, well served, and clean; in others it is far from sufficient, and can scarcely be qualified as wholesome. In provision shops the assistants often come off badly, inasmuch as they are made to eat that which cannot be sold. An assistant working for a large store of this description informed us that in the morning he was given what he defined as "an apology for coffee" and two, or at most three, slices of bread-and-margarine. For the midday meal there was one helping of meat, but this too frequently proved to be Ostend rabbit, for the simple reason that these rabbits will not keep long, and sometimes cannot be sold. In the afternoon there were tea and a round and a half of bread-and-butter. Finally, at 11 o'clock, on going to bed, the assistants were given, in their bedrooms, a small piece of bread, a small piece of cheese, and a glass of water. It would be easy to contract for this style and amount of food at 7*s.* 6*d.* per week per head. Those assistants who were so far privileged as to be permitted to take their meals out of doors had 12*s.* extra wages allowed, and with this they obtained much better board. Another shopman complained of his employer, who had made a bad speculation in pickled pork, and consequently fed his assistants on his superfluous stock for three months. On Saturday nights assistants are always very eager to sell off the stale remnants, so that they may not have to eat them themselves the next day. Several grocers' and cheesemongers' assistants frankly declared that if their appetites were satisfied, it was only because they helped themselves to such things as eggs, cheese, rashers of bacon, cocoa, &c., which could be abstracted from the general stock without attracting notice. They argued they had undertaken to work for food and wages, and conceived that, if they had not enough food, they had a right to help themselves to more. The impression seemed to prevail that assistants in small drapers' shops were the worst fed, and a sensational story was told us of a draper in a West-end suburb. This draper was stated to have usually gone to a butcher's between eleven and twelve o'clock on Saturday nights, just when the shop was about to close. He would then offer to purchase all the remnants, or "block ornaments," at 2*d.* a pound. As these fragments at so late an hour could not be sold, the butcher generally accepted the offer, and the draper, having arranged a method for keeping this meat in ice, fed his assistants with it during the ensuing week.

Though we may hope and believe that such bad and insufficient meals are altogether exceptional, there is one grievance which is not at all exceptional, but is, on the contrary, very general in almost every branch of trade. We allude to the shortness of the time allowed for meals. Very frequently only a quarter of an hour is given for tea and breakfast and half an hour for dinner. This is altogether insufficient in itself; but in very large establishments it sometimes takes nearly five minutes to go from the counter to the dining-room, so that the food has to be consumed in great haste. In small shops assistants are often called away in the middle of their meals to serve customers. All this naturally tends to interfere with the process of digestion, and dyspepsia is very prevalent among this class of workers.

Over-worked, under-paid, and under-fed during the day, the shop assistant is scarcely more fortunate at night. The sleeping accommodation, when this is provided, also escapes all sanitary control. The Common Lodging Houses Act protects vagrants and vagabonds generally when they resort to the poorest lodging-houses, but there is no measure that establishes any sort of supervision over the sleeping accommodation given to the shop assistant. There are consequently many gross abuses. An assistant described to us that where he worked he slept with seven others in a very small room. At half-past seven in the morning they had to be up to open the shop. In their room there was absolutely no furniture—nothing but beds,—and to wash they had to descend three flights of stairs, where there was a lavatory provided for all the shop assistants, numbering in all thirty-six persons, some of whom sleep outside. At ten o'clock the shop is closed, but it takes about twenty minutes to put various things in order, so that the assistants cannot get out for exercise and recreation before 10.20 at night, and they must be back in their bedrooms by eleven o'clock. There is no time for reading or self-culture; it means practically life from bed to the counter and from the counter back to bed. On Sunday mornings only can they indulge in a more lengthy rest; but even on Sundays they are all obliged to turn out of the bedrooms by 10.30 A.M., and those who have no friends or family to visit spend a wretched holy day. They are not allowed to go to their room, and if they were there is no fire or furniture; they cannot sit, read, or otherwise rest and amuse themselves. They must go out whether the weather be fair or foul. This is no solitary case. Shop assistants have no residence, no home, but merely a room at the top of the house—sometimes a mere attic,—where as many beds as possible are crammed in together. Here the shop assistant may throw himself wearily down and snatch a few hours' sleep; but this bare, fireless, overcrowded room is no home to him. Thus, on the Sunday, when the shop is closed he must go out somewhere, and if he has no friends to visit must wander listlessly about the streets or parks. These homeless wanderers may be noticed on Sunday in great numbers, especially in Regent's Park. On week days also, between ten and eleven at night, the shop assistant is frequently driven out into the streets. The shopkeeper lives on the premises with his family, and does not care for his assistant or assistants to come into the private part of the house before it is actually bedtime. Yet what sort of walk, exercise, or recreation can a shop assistant take between ten and eleven at night? It too often results, especially when the weather is not fine, in his seeking rest and refuge at the public-house bar. Nor are female shop assistants better accommodated so far as their sleeping rooms are concerned. It is not to be expected that petty tradesmen should possess any special knowledge of the laws of health. Ignorance, indifference, or motives of economy lead them to set such considerations at defiance. One case was mentioned to us of a draper who was alleged to have screwed down the window of the room where his female assistants sleep. Presumably he feared that his assistants might communicate from the window with persons outside; but the result is that the room is never aired, and in the event of a fire the girls could not escape. Another case was brought to our notice of a girl, an apprentice, who was discharged from a draper's shop because her health had broken down. She is only eighteen years old, and maintains that, if her health has failed her, it is in consequence of the insufficient food and bad treatment she received. The sheets of her bed, she declared, were only changed once in three months, and the charwoman who works on the premises corroborated this information. Even worse than all this, shop assistants sometimes have no bedrooms at all, but are expected to sleep in the shop under the counter. This is especially the case in pawnbrokers' shops. One assistant assured us that he had slept for seven years under the counter of a pawnbroker's shop. He had served, to use his own expression, "as a cheap shop dog." But though apparently a strongly built man, his health had finally given way. The crowd of people, the flare of gas, the impossibility of thoroughly renewing the air in the pawnshop, had at last told on his constitution, and, acting under medical advice, he was ultimately induced to leave this pawnbroker's shop and seek employment where it would be possible to sleep in more wholesome quarters.

Such are some of the grievances which the shop assistants have borne with much patience for too long, and our list is far from exhausted. As yet we have only described what shop assistants with whom we have personally come in contact have endured. Even though these may be qualified as altogether exceptional cases, they have remained for years undetected and undisturbed. Exceptional such abuses may be, but what is there to prevent them becoming more general? In taking up, however, evidence other than that which we ourselves have gathered, we find that many of the abuses to which we have alluded are far from exceptional. It remains for us therefore to deal with the question in a more general sense, and then to examine what little has been done to improve the condition of shop assistants, notably the providing of seats and the

Digitized by Google

movement for early closing. Finally, we may be tempted to consider what further remedial measures naturally suggest themselves.

(To be continued.)

THE FINANCES OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THEIR RELATION TO THE REFORM OF THE COLLEGE.

IN the struggles and debates at the Royal College of Surgeons of England neither the Fellows nor the Members have made sufficient use of the materials for argument which may be derived from the tables of income and expenditure published annually in the Calendar of the College. Beyond casual references to the large sums expended in bricks and mortar, the handsome emoluments of examiners elected out of the body which distributes the revenue of the institution, the injustice of excluding altogether from power or influence the very persons to whom the College is indebted for its existence and prosperity, and a stray resolution to the effect that the Fellows and Members ought to be consulted in regard to any extraordinary expenditure, we cannot recall anything approaching to effective criticism. And yet we believe that a close examination into the present condition of the income and expenditure of the College—which it is the business and duty of the Fellows and Members to watch, and, if possible, to control—will furnish one of the most effectual weapons ever placed in the hands of the friends of reform and of a liberal constitution, and, if properly utilised, will effectually prevent the continuance and augmentation of the power at present wielded by the Council of the College. As we cannot pretend to deal exhaustively with this subject within the limits of a single article, we shall direct attention to the salient features of the financial position and show how they support the principles of constitutional reform which have again and again been urged upon the attention of the Council of the College.

1. It must impress itself strongly on all who inspect the balance-sheets how large a revenue is annually administered by the Council, large both absolutely in itself and relatively to that at the command of similar institutions where a far more liberal constitution prevails. In 1890–91 the total income of the College amounted to no less a sum than £27,174. We have not the material before us for making any close comparison between the College of Surgeons of England and the other professional Colleges, as the balance sheets of the latter are not readily accessible; but, judging by returns furnished a few years ago, it may be concluded, we believe with a fair approach to accuracy, that the income of the Royal College of Surgeons of England varies from about nine times to two and a half times as much as that of the other Colleges.

2. On comparing the income of the College for 1890–91 with that of preceding years, a considerable increase will be observed. Ten years previously—viz., in 1881–82—the income was £18,578, or £8596 less than in 1890–91. Part of the increase is due to the larger receipts from the Membership examinations, for in 1881–82 the receipts from this source were £13,191, and in 1890–91 £17,122. In the intervening years the receipts fluctuated considerably, owing chiefly to the introduction and working of the Conjoint Examining Scheme. The most fruitful year of the decade was 1886–87, when the receipts from the Members' examinations rose as high as £20,977. The whole of this large sum was derived from the strictly professional examinations, for the Preliminary examination conducted by the College, which used to yield about £700 per annum, was discontinued in 1881–82. The rest of the increase of income has been due to the Erasmus Wilson bequest. The stock dividends from this source accrued in 1887–88, and in 1890–91 amounted to £5438.

3. It is a very striking fact, and one of the utmost importance for the reformer to note, that not far short of £20 000 out of the £27,174 of the income of the College in 1890–91 were derived from the professional examinations. The exact sum was £19,393 17*s.* 6*d.*, comprised of £17,122 17*s.* 6*d.* from the Members' examinations, £1830 from the Fellows' examinations, and £441 from the Dental examinations. Thus the receipts from the Members' examinations were more than nine times as great as those from the Fellows' examinations. For a strict and fair comparison, however, between the receipts from the Members and the receipts from the Fellows, it would be necessary to deduct from the £17 000 received from the Members' examinations the sums paid by those who subsequently obtain the Fellowship, and to add this to the receipts from the Fellows' examinations. This adjustment would lessen the disproportion between the two sources of income, but would scarcely make the receipts from the Fellows amount to more than one fifth or one-sixth of the receipts from the Members of the College.

4. It may not be generally known that nearly all the fees derived from the candidates for the Fellowship examination are absorbed in expenses. On the first Fellowship examination there is a surplus, but the final Fellowship examination entails no inconsiderable loss to the College, the balance being barely redressed when the surplus from the first examination is set off against the deficit on the final. The result is that the receipts from the Fellowship examinations contribute little towards the maintenance of the College establishment. How much the Members contribute was most forcibly shown a few years ago by Mr. Erichsen in a well-remembered speech at the College, afterwards published as a pamphlet, composed, curiously enough, to prove that the Members ought to be excluded from a share in the government of the College. Mr. Erichsen said that "the fees paid by the Members sufficed, not only to pay the Board and Court of Examiners, to buy the diploma stamps, to defray at least two thirds of the working expenses of the College, mainly due to the requirements of the examinations, and nearly the whole of the cost of maintaining the museum and library, but to leave a balance of £6000, out of which pensions and various other collegiate expenses were paid. Out of each diploma fee of 20 guineas 6 or 7 guineas went into the coffers of the College."

The foregoing remarks concern the income of the College. We turn now to the expenditure. The most noteworthy points in regard to the expenditure are these:—

5. The whole of the income is absorbed by the expenditure There is no margin. Neither last year, 1890–91, nor for several years, has there been any fresh investment out of the income of the College. The expenditure, ordinary and extraordinary, has both diminished capital, and has more than swallowed up the interest on the Erasmus Wilson stocks.

6. The Examiners of the College received about one-third of the income for 1890–91. They divided between them as nearly as possible £9000. The percentage proportion of examiners' fees to receipts works out to about 42 in the case of the Members' examinations, and to about 82 in the case of the Fellows' examinations. For the benefit of the examiners there is a capitation fee on each candidate examined, whether accepted or rejected, so that a rejected candidate may involve a loss to the College, but not to the examiners.

7. The working expenses of the examinations exclusive of examiners may be reckoned as not less than 20 per cent. Hence there would be a balance of between 30 and 40 per cent. on Members' fees available for the general expenses of the College, but on the Fellows' fees little if any.

8. During the last few years three new sources of expense have been opened—the Examination Hall and the laboratories on the Embankment, and the enlargement of the College by the addition of new museums &c. In ten years more than £62 000 have been expended on bricks and mortar and buildings generally. In 1890–91 the proportion of expenses paid by the College for the Examination Hall was £4274 12*s.* 4*d.*, and the laboratories cost £1434; but as £761 were expended on furniture and fittings, the annual cost for the future may be reckoned as less than £1000. We have no means of estimating accurately the additional expenditure caused by the new buildings at the College itself, but the whole cost of maintaining the three new establishments may be put down in round numbers at £6000 annually.

9. If the receipts from examinations and trust funds are set aside, and regard paid only to the fixed income and necessary expenditure, there is a considerable annual deficit. The fixed income of the College from rents and stock amounted in 1890–91 to £6807 7*s.* 3*d.*, and the necessary expenditure—i.e., the expenditure for maintenance of the establishment—was about £9500. In other words, there was

Digitized by Google

a deficit under the present administration of the College of nearly £2700. The deficit is likely to be greater this year, for there is a debt of £11,000 under existing contracts, and this must be met by a fresh sale of stock, which will still further diminish the fixed income. The receipts from house property have been recently reduced by more than one half—viz., from £1500 to £700—in consequence of the demolition of houses to admit of the enlargement of the College; but it is only fair to state that No. 44, Lincoln's-inn-fields had been purchased five years previously, and this brought £500 a year into the College coffers. It has now gone, however, with a great deal more of the capital, and at the present rate of expenditure the whole of the capital will disappear in a few years.

10. Of the £9000 devoted to the payment of examiners, about £5500 are distributed among the ten fortunate members of the Court of Examiners, and of this £5500 seven-tenths, or £3850, replenish the pockets of seven members.

The conclusions which we draw from the foregoing facts are these:—

1. £27,000 a year and upwards is a very large sum for a corporation to receive and expend, and for a Council of twenty-four persons only out of 16,000 to claim and exercise the right of expending it, as well as of disposing of the capital belonging to the corporation, without submitting their stewardship to the Fellows and Members who constitute the corporation for unfettered and open criticism is an anachronism at the end of the nineteenth century.

2. The enormous preponderance of the contributions of the Members of the College over those of the Fellows, and the fact that from Members' fees alone is derived money for defraying the working expenses of the institution, show the absolute injustice of excluding the Members from any share in the government and in the election of the Council. Let it be noted that the cost of maintenance of the Examination Hall and laboratories—new sources of expenditure—equals the new source of income, the dividends from the Erasmus Wilson stocks, so that without the Members' fees the College itself could not be maintained.

3. To have expended £73,000 on buildings in a few years without the sanction of the Fellows and Members is morally at least an abuse of power, whether the money has been rightly and judiciously expended or not. It is true that there is nothing in the Charters to prevent this, and the Council have acted strictly within the letter of the law. The Charters, however, on which the present constitution is based are from nearly a hundred to fifty years old, and from recent experience it appears that the Privy Council will not act in opposition to the governing body of a corporation in amending Charters, whatever may be the weight of evidence and argument adduced in favour of the desired amendments. And yet if a Charter had now to be granted for the first time, it would scarcely be framed in so illiberal a spirit. All the circumstances have changed. The College has grown into a rich corporation, and has attained an importance which it did not possess a hundred or even fifty years ago. If all the facts could be laid before Parliament and thoroughly investigated and mastered by the members, there can be little doubt that large concessions would be made to the Fellows and Members, and some check be imposed upon the autocracy of the Council.

4. The present expenditure at the College ought to be reduced so as to ensure a margin sufficient to admit of a substantial annual investment, for the purpose of bringing up the fixed income to a level with necessary expenditure. Instead of being paid out of capitation fees, fixed salaries should be given to the examiners, and these should be calculated after due allowance had been made for meeting the necessary expenditure and providing a surplus for investment. Whilst cordially endorsing the view that examiners should be well paid for their services, we think that the work could be well done for £300 a year, and there would be no lack of thoroughly competent candidates for the appointments.

SCOTTISH UNIVERSITIES' COMMISSION.

A FEW days ago Ordinance No. 16 (Edinburgh, No. 1 Regulations for Degrees in Medicine) was issued. Its permanent form is more satisfactory than its draft form was. Four degrees in medicine and surgery are to be conferred by the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). After dealing with the preliminary examination, the general lines of which are much the same as those at present in operation, it proceeds to regulate professional education. Of the five years devoted to professional study, during at least three of them hospital practice is compulsory, and during the fifth year candidates must be engaged in clinical study for nine months. Not less than nine months' attendance on clinical surgery and clinical medicine are made compulsory, as against six months, which is the present arrangement. Practical pharmacy, to which such prominence was given in the draft ordinance, and regarding which there was almost unanimous disapproval expressed, save by those specially interested in the teaching of the subject, has been reduced to its proper place, twenty-five meetings of a practical pharmacy class or three months' dispensing in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society, being now all that is required. Candidates must have acted as clerk in the medical house and dresser in the surgical wards, and they must have availed themselves, to such an extent as may be required by the Senatus, with the approval of the University Court, of opportunities of studying at a hospital or dispensary, post-mortem examinations, fevers, diseases of children, ophthalmology, or such other special departments as may from time to time be determined. A course of instruction in mental diseases has also been made compulsory. An important modification of the present system has been made possible by its being made the duty of the professors and lecturers to submit to the Senatus annually a scheme specifying what proportion of the courses should be devoted to lectures, practical demonstrations, examinations, and tutorial work respectively, and the Senatus shall transmit such scheme, with such observations as it may think fit to make thereon, to the University Court for its approval. At present the statutory regulation is that 100 lectures must be delivered to constitute a winter course.

The professional examinations are to be four in number—viz (1) botany, zoology, physics, and chemistry; (2) anatomy, physiology, and materia medica and therapeutics; (3) pathology, and medical jurisprudence and public health; (4) surgery and clinical surgery, practice of medicine and clinical medicine, and midwifery. For the first group candidates may present themselves at the first examination held after they have attended a complete course. The second examination comes off at the end of the third winter session, the third at the end of the fourth winter session, and the final at the end of the fifth year of study. The result of the arrangement will probably be that students will devote too much of their energy during the fourth year to these subjects. For the degrees of Doctor of Medicine and Master in Surgery a special examination has been instituted in addition to the presentation of a thesis.

Ordinance No. 12 (General, No. 7, Regulations for Degrees in Science) was issued at the same time. As regards degrees in pure science, it is ordained that there shall be a first science examination in (1) mathematics or biology (i.e., zoology and botany); (2) natural philosophy; (3) chemistry; and a second examination in any three or more of the following:—Mathematics, natural philosophy, astronomy, chemistry, human anatomy (including anthropology), physiology, geology (including mineralogy), zoology (including comparative anatomy), botany (including vegetable physiology). Provision is also made for the establishment of degrees in applied science by the University Court in each University.

UNIVERSITY RIOTS IN ITALY.

A MORAL cyclone has agitated the groves of the Italian Academa. Beginning at the University of Naples, where a law professor inflicted personal chastisement on a contumacious student, the disturbance has involved the whole academic life of Italy, till not a single seat of learning from Turin to Palermo, from Padua to Cagliari, has escaped. So wide has the chasm between professors and students become that in the majority of the schools all work has been suspended, and the time that should have been devoted to tuition on the one hand and to classes on the other has been filled by indignation meetings of the insubordinate youths

Digitized by Google

and deliberative councils of the offended professoriate. For two months this state of things has prevailed, and there seemed little prospect of its calming down. The students, on their side, complain of the severity of the regulations they have to observe, the unyielding spirit of the University authorities in the matter of attendance and of examination, the summary way in which they are "remitted to their studies," and the consequent loss of time they incur before graduation and the commencement of professional practice. The professors, with more justice, insist on obedience to the traditional University system; on the fatal results of relaxed discipline and the lowering of professional qualification; and, above all, on the necessity of initiating such reforms as may be called for in a rational and regular way. There can be no doubt that the professors are in the right, though some of them may have lost temper and furnished the students with a too welcome excuse for continued agitation. The Minister of Public Instruction (Signor Villari) has, under great provocation, acted with judgment, if not at first with much energy—deterred, no doubt, from taking severer measures by the well-known sympathy the students can always count upon from the Extreme Left of the Italian Chamber. And here lies the explanation of a good deal of the difficulty under which academic life in Italy labours. All Italian students are more or less politicians. The generation which contributed to the unity and independence of the kingdom still gives the tone to young Italy. Commemorations of patriotic deeds and of patriotic heroes recur at intervals so frequent that the country is never for more than a few weeks at a time allowed to forget the revolution under which it rose to freedom and power, and those periodical *feste* appeal with peculiar effect to the academic youth. Studies are suspended on such occasions for mental stimulus of a far less wholesome kind, and the desire to shine as a "patriotic orator" overrides the soberer ambition to excel in academic work. Brought into the closest contact with the "party of action" and its leaders, the students regard these as their special friends, whose applause they are more eager to win than that of their teachers and professors. It is significant in this connexion to read that the disturbances of the last few months have been started and kept up by a few ringleaders in each University—ringleaders whose demagogic abilities and achievements have won them the sympathy of politicians of the Extreme Left. These youths are confident of the support they will have in the Chamber of Deputies should their conduct come up for consideration before that body; hence the spirit of impunity they manifest, and hence the reluctance of the Minister to court a collision in Parliament. That reluctance, however, Signor Villari seems now to have overcome; while the summary example made of three of the students in the Roman University, though for the moment it has been followed by fresh acts of insubordination and violence, cannot but have a salutary effect. The better class of the academic youth are now venturing to assert themselves, and in some cases are coöperating with their professors in restoring order for the resumption of study. Attempts to "boycott" them (for such tactics have found their way into University life) are being successfully resisted, and ere long we hope to hear of a vigorous combination of the healthier and manlier constituents of the schools for the vindication of what are, after all, their higher interests. The weakness of Signor Villari's predecessors themselves, tainted with the demagogic spirit, is blamed for the growth of the insubordination now so unhappily prevalent—their too great indulgence of political extravagance among the students having borne its inevitable fruits. But, to judge from the Italian press of all party shades, except that of the Extreme Left, public opinion is seconding the enlightened Minister in supporting the University authorities; while the Government, now that it is appealed to, have but to show an unyielding front to put an end to disturbances which must throw back the higher education of Italy for years, unless vigorously and relentlessly put down.

SYDNEY HOSPITAL.—A radical mode of dealing with doubtful hospital buildings has been undertaken by the authorities of the Sydney Hospital. The wooden buildings at present in use are to be destroyed by fire, and the sum of £25,000 is to be devoted to improving and extending the hospital premises.

FOOT-AND-MOUTH DISEASE.

SODIUM DITHIOSALICYLATE (NOS. 1 AND 2 DITHION) AS A REMEDY.

THE increase in the epidemic of foot-and-mouth disease, and the enormous loss it entails either upon the farmer or upon the local rates, give very great interest to the observations of Dr. Renner, district veterinary surgeon, Dieburg, which have been published in a recent number of the *Berliner Thierarztlichen Wochenschrift*. He states that, during an extensive outbreak of foot-and-mouth disease in 1890 and 1891, he employed the two dithion preparations with great success. At first they were used externally only, those parts of the animals where pustules had formed and inflammatory processes set in—the mouths, udders, feet, and hoofs—being painted every three hours with a 2½ to 5 per cent. solution, washed and bandaged. He found that the pustules disappeared so rapidly that in two or three days a perfect cure was obtained. Cracking of the nipples or sealing of the udders was rare, the solution acting as an aseptic varnish to all wounded places. Malignant suppuration or loss of the hoofs—sequelæ which often necessitate slaughtering the animals—did not occur in animals treated in this way.

Professor Rosenbach of Breslau having reported favourably upon the internal employment of dithions, Dr. Renner repeated his experiments and found that ruminants were thus mostly protected against the disease, while those attacked rapidly recovered without serious injury. In these experiments from 1 to 2 oz. daily were given internally in the food, and 2½ to 5 per cent. solutions were applied externally. Details are given of the many occasions upon which this plan of treatment was followed, and Dr. Renner points out that, although the chief objection to this treatment is the cost of the remedies, this is really insignificant when compared with the enormous loss which is thus saved. A dithion compound has been now prepared at nearly one-fourth of the original price, and this has been used by Dr. Renner in two places with similar satisfactory results. To make certain of its efficacy numerous healthy animals were intentionally inoculated, and under this treatment they passed through the disease and recovered in about twelve days. Dr. Renner considers that he has proved that dithion, if used early, protects from the foot-and-mouth disease, that it diminishes its intensity when it has already broken out, and that it reduces the losses and restricts the attack to the affected herd. These conclusions have subsequently been supported by a farmer, who spoke enthusiastically of the benefits obtained from dissolving the preparation in the form of a powder in water, and using part of the solution to wash the mouths, hoofs, and udders of the sick animals, while the greater portion was mixed with the drink and was readily taken.

The present is an opportune moment for the publication of these observations, since, if they are confirmed, they will entail a great saving of animal life, and will thus largely rob the epidemic of its terrors.

THE MEDICAL DEFENCE UNION.

THE annual meeting of the Association was held on Wednesday, at 20, Hanover-square. There was a large attendance of members. The chair was occupied by the President, Mr. Lawson Tait. In submitting the report, Mr. Tait pointed out that no record of work done could be more satisfactory. Every conceivable kind of difficulty that could arise in the life of individual medical practitioners had been met, and a satisfactory issue arrived at. The society, existing as it did for purely fighting purposes, had never lost a case it had taken in hand. The report proved the absolute need of such an institution. Many men had been hardly used by reason of their inability to help themselves, and the report recorded a large number of successful cases which showed that the evils incidental to medical men had not been misrepresented either in degree or in kind. The cases which had occurred in Sunderland would illustrate that statement. The machinery existed whereby designing people could now be brought to justice, and other

Digitized by Google

malicious persons put on their guard lest they should meet a similar fate. In many instances charges of a ruinous character had been settled by as many postage stamps as the charge itself involved. The items of the report showed that the expenditure had been extremely small, and the balance in hand was large enough to enable the society to fight a reasonably large suit without calling upon their guarantee fund. Any serious expenditure of money would be involved only when cases of fresh difficulty occurred. The moral weight of a large body of members of the profession united together with an honest, legitimate, and determined purpose would have more effect than any amount of litigation. The report and the treasurer's accounts were adopted unanimously. Under the new Articles of Association an executive council of twelve members was nominated and appointed. The President considered that the more narrowly the work was confined to the protection of the individual practitioner the more successful the Union would be. There already existed power enough for political agitation, and it would be impossible for those who had taken any energetic part in the work of the Association to agree to anything by which its success would be weakened. The actual state of the law made it necessary to act on the lines of a limited company. Any departure from these lines might, in any given case, render the Society liable to be surcharged with costs of both sides. They had to move with the greatest care, and it was for these reasons that the reconstruction of the machinery had become necessary, and had been accomplished. The twelve elected members were to constitute a nucleus. Continuity of action would be secured by electing three members yearly. The members did not want any cataclysmic upsetting of the Union, and if they were at any time dissatisfied with the conduct of the Council a vote of censure would, according to the usual method, secure the immediate resignation of all its members.

Dr. Bridgewater nominated Dr. Masters, Dr. Campbell Pope. Dr. Felce, Dr. Danford Thomas, Dr. Bantock, Dr. Bateman, Mr. Lawson Tait, Mr. Justin McCarthy, Dr. Barling, Mr. Messiter, Dr. Hallwright, and Dr. Leslie Phillips. This Council was unanimously appointed.

THE LATE SIR PROVO WALLIS, G.C.B.

THE great age (100 years and ten months) attained by this distinguished naval officer, together with his world-wide reputation as the hero of the *Shannon-Chesapeake* sea-fight, may give some interest to the following notes of his health from December, 1890, to the time of his death, with which we have been supplied through the kindness of Mr. L. E. W. Stephens, his medical attendant.

On Dec. 6th, 1890, in the afternoon, I was called for the first time to Sir Provo Wallis. I found him in bed clothed in an ordinary longcloth nightshirt, a linen nightcap, linen sheets to the bed, and no fire in the room. He complained chiefly of discomfort with waterbrash after meals, for which lactopeptine powders were prescribed with great benefit. He was unable to lie straight in bed, but was lying on his right side with his knees semi-flexed, elbows flexed, and forearms folded across the chest. Movement of the legs fairly good, movement of arms limited, so that he could only just raise himself on his elbows. There was no paralysis, only wasting of muscles from disuse. Over each great trochanter was an oval bedsore 2½ by 2 in., in process of healing. Micturition was frequent, painful, and uncertain. Hands and feet cold. Pulse 70, with occasional intermission, the left pulse being much weaker than the right. Temperature 97°. Mental condition and memory very good. No teeth; tongue clear; eyesight good; slightly deaf. Heart and lungs normal. Urine occasionally ammoniacal, with deposit of muco-pus. Bowels costive, so that about every fourth day great effort was required in defecation. Much troubled with pruritus. To relieve these troubles a fire was ordered in the bedroom to raise the temperature gradually from 38° or 40° to between 50° and 60°. The patient was placed on a water-bed filled with warm water, and by degrees was clothed in flannel and placed between blankets, all of which met with sturdy opposition from the patient. Catheterisation, when suggested, was firmly declined. By careful dressing the bedsores soon healed, and the skin remained sound for months. With copious draughts of lithia water the cystitis cleared up. During February and March, 1891, visits were made on alternate days. In April, May, and June a weekly visit sufficed.

In November the same helpless condition existed, and a distaste for food gradually came on, with secretion of very tenacious mucus from the pharynx during deglutition. The efforts required to expel this mucus caused great distress and exhaustion. In December occurred a blocking of the rectum with hard, smooth, round scybala difficult of removal. The bowel was cleared out every fourth day. Towards the end of December the patient would frequently take no food from 7.30 one morning until the following day at the same hour. This meal consisted of a pint of cocoa and milk, with rusks soaked in it. The cicatrices of the bedsores broke down into a number of small round wounds. Lastly, gangrene set in on Feb. 9th, terminating painlessly and fatally on Feb. 13th.

THE BRITISH INSTITUTE OF PUBLIC HEALTH.

THIS is an Association of medical men possessing registrable qualifications in State medicine, public health, or sanitary science, medical officers of health, and others. The Council of the Public Health Medical Society have been successful in obtaining incorporation by special licence of the Board of Trade under the above title, with the object of aiding theoretical and practical investigations and study of all branches of public health medicine. They will also hold meetings, congresses, institute lectures, and demonstrations; they propose to issue publications of the Transactions of the Association, to found a library, and to publish a journal. Among other objects which the Association has in view is the examination of candidates, either alone or in conjunction with one or more kindred bodies, and the granting of certificates of proficiency as sanitary inspectors. The members of the Institute consist of fellows, ordinary members, and associates, and it is provided that the first fellows of the Institute shall consist of the present members of the Public Health Medical Society, or such of them as elect to become such; all subsequent fellowships being conferred by the Council upon such persons as possess a registrable qualification in sanitary science, public health, or State medicine, in accordance with the Medical Act, 1886, Section 21. The Council are taking immediate steps to found branches in each division of the kingdom.

The articles and memorandum of association were signed by Dr. Littlejohn (Edinburgh), Dr. Grimshaw (Registrar-General for Ireland), Dr. Meymott Tidy, Dr. Mumby (Portsmouth), Sir Charles Cameron, Sir Douglas Maclagan, Dr. W. R. Smith, and Dr. Francis Allan.

CONCERNING THE PROPOSED GRESHAM UNIVERSITY.

THE following statement has been forwarded to every member of Parliament:—

SIR,—The Medical Schools of London, which include some 300 teachers and 2000 students, have united with University College, London, and King's College, London, in efforts to obtain the Charter for the Gresham University, now on the table of the House. They venture to ask for your support in Parliament because they believe that this University will be of the greatest advantage to students and teachers in London, in that it will tend to develop in every way the exceptional means of instruction afforded by the metropolis. This remark applies especially to Medicine, in which the opportunities of study must, from obvious causes, be greater than in any other city.

It is the desire of the supporters of the Charter, including all the medical schools, to have in London a local university which shall give its students all those academical advantages in learning and graduation which already exist in the Universities of Oxford, Cambridge, Edinburgh, Aberdeen, and Glasgow.

It has been objected in a statement circulated by the Victoria University that Gresham degrees may be given too easily, especially in respect of the standard of scientific attainment. On the part of the London Medical Schools—and we know it to be equally true of the other faculties—we can assert that nothing of the kind is contemplated. We are not less aware than the authorities of other medical schools of the importance in medical education of a good groundwork in arts and science. The education given by us is, we believe, as thorough as any

Digitized by Google

in Europe, and the degree will represent that education, together with examinations, which will not seek to attract students by their inferiority. The whole body of the medical teachers of London, containing as it does a large proportion of the most distinguished physicians, surgeons, and teachers of science in the United Kingdom, may surely be accorded the trust given to the teachers in universities elsewhere.

Some of the details of the statement of the Victoria University are inaccurate, and on other points as to the intentions of the proposed University—mere assumptions are put forward.

It is not true that Medicine is paramount upon the Governing Body of the University, or that it has a larger representation than is required by the numerical strength of the Faculty and the variety of circumstances in the Teaching Institutions. The Council will consist of at least forty members, of whom not more than fourteen will certainly be, and not more than sixteen are likely to be, representatives of Medicine. Of the interests of science the constitution of the University supplies a special guarantee in the organisation of the teachers by Faculties, not by Institutions, as in the Victoria University.

The statement circulated by the Schools of Medicine in Birmingham, Bristol, and Sheffield repeats the arguments, and closely follows the lines of that put forward by the Victoria University. Any attempt on the part of these schools to obtain for themselves the advantage of association in a Teaching University will have our sympathy, but it would be a great injustice that in the meantime London should be refused this privilege.

The Charter of the Gresham University grants what we have for many years endeavoured to obtain, and, in the interests of medical education in London, we earnestly hope that the University may be established on this basis.

We are, Sir, your faithful servants,

STANLEY BOYD,*
For the Charing-cross Hospital Medical School, a College (designate) in the University.

FREDERICK TAYLOR,
For the Guy's Hospital Medical School, a College (designate) in the University.

* Hon. Sec. to the Committee of the Delegates of the Metropolitan Medical Schools.

Feb. 17th, 1892.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5137 births and 4125 deaths were registered during the week ending Feb. 20th. The annual rate of mortality in these towns, which had declined in the preceding four weeks from 35·4 to 23·1 per 1000, further fell last week to 21·1. In London the rate was 20·7 per 1000, while it averaged 21·4 in the thirty-two provincial towns. The lowest rates in these towns last week were 13·0 in Derby, 15·5 in Bradford, 15·7 in Sunderland, and 16·9 in Wolverhampton; the highest rates were 26·4 in Oldham, 26·5 in Burnley, 27·7 in Blackburn, and 28·2 in Preston. The 4125 deaths included 383, which were referred to the principal zymotic diseases, against numbers declining from 604 to 386 in the preceding five weeks; of these, 177 resulted from whooping-cough, 86 from measles, 48 from diarrhœa, 29 from diphtheria, 23 from scarlet fever, 18 from "fever" (principally enteric), and two from small-pox. No fatal case of any of these diseases was registered either in Plymouth or in Hull; in the other towns the lowest zymotic death-rates were recorded in Brighton, Croydon, and Derby, and the highest in Liverpool, Burnley, Cardiff, and Blackburn. The greatest mortality from measles occurred in Liverpool, Swansea, Norwich, and Sunderland; from scarlet fever in Cardiff; from whooping-cough in London, West Ham, Manchester, Barnley, Sheffield, and Bristol; from "fever" in Blackburn; and from diarrhœa in Nottingham, Preston, and Blackburn. The 29 deaths from diphtheria included 15 in London, 3 in West Ham, 2 in Manchester, and 2 in Sheffield. One fatal case of small-pox was recorded in Liverpool and one in Oldham, but not one in any other of the 33 large towns; 7 small-pox patients were under treatment in the Metropolitan Asylum Hospitals, and 1 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of last week was 1116, against numbers declining from 1397 to 1244 at the end of the preceding four weeks; 82 new cases were admitted during the week, against 100 and 117 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 1465 to 560 in the preceding four weeks, further fell last week to 459, and were 46 below the corrected average. The causes of 96, or 2·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Portsmouth, Oldham, Sunderland, and in four other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Bolton, Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the preceding four weeks from 27·2 to 20·8 per 1000, further fell to 20·1 during the week ending Feb. 20th, and was 1·1 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·8 in Paisley and 17·1 in Edinburgh to 21·5 in Glasgow and 23·1 in Greenock. The 559 deaths in these towns included 15 which were referred to whooping-cough, 13 to diarrhœa, 10 to "fever," 9 to measles, 8 to diphtheria, 7 to scarlet fever, and not one to small-pox. In all, 62 deaths resulted from these principal zymotic diseases, against 55 and 46 in the preceding two weeks. These 62 deaths were equal to an annual rate of 2·2 per 1000, which was slightly above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had increased from 16 to 22 in the preceding three weeks, declined last week to 15, of which 10 occurred in Glasgow and 2 in Paisley. The 13 deaths from diarrhœa showed a further increase upon recent weekly numbers, and included 6 in Glasgow. The fatal cases of "fever," which had been 8 and 3 in the previous two weeks, rose again last week to 10, of which 6 occurred in Glasgow. Of the 9 deaths referred to measles, 5 were recorded in Glasgow and 4 in Edinburgh; and of the 8 fatal cases of diphtheria, 3 occurred in Glasgow and 2 in Aberdeen. The 7 deaths from scarlet fever showed a further increase upon recent weekly numbers, and included 5 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had declined in the preceding four weeks from 230 to 146, rose again last week to 154, and exceeded by 14 the number in the corresponding week of last year. The causes of 56, or 10 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the four preceding weeks from 54·1 to 31·8 per 1000, rose again to 37·4 during the week ending Feb. 20th. During the first seven weeks of the current quarter the death-rate in the city averaged 39·6 per 1000, against 33·7 in London and 20·3 in Edinburgh. The 251 deaths in Dublin during the week under notice showed an increase of 38 upon the number in the preceding week, and included 4 which were referred to diarrhœa, 3 to measles, 3 to whooping-cough, 2 to scarlet fever, 1 to enteric fever, and not one either to small-pox or diphtheria. In all, 13 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1·9 per 1000, the zymotic rate for the same period being 2·4 in London and 2·2 in Edinburgh. The fatal cases of whooping-cough, which had been 2 and 3 in the preceding two weeks, were again 3 last week. The 3 deaths referred to measles exceeded the number in any recent week, and the 2 fatal cases of scarlet fever were the first recorded within the city since October last. The 251 deaths in Dublin last week included 39 of infants under one year of age, and 78 of persons aged

Digitized by Google

upwards of sixty years; the deaths both of infants and of elderly persons showed an increase upon the numbers recorded in recent weeks. Three inquest cases and 4 deaths from violence were registered; and 102, or 40 per cent., of the deaths occurred in public institutions. The causes of 30, or 12 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

HER MAJESTY'S ARMY AND INDIAN MEDICAL SERVICES.

THE following are the questions set to candidates for the Military Medical Services at the recent examinations:—

Natural Sciences.—Zoology: 1. Refer to its sub-kingdom and class an animal with the following characters, and give examples:—Body with transverse segmentation; a ganglionated ventral chord; head, thorax, and abdomen distinctly separated; respiration by trachea. 2. What are the essential characters by which the *coelenterata* are distinguished as a separate group of the animal kingdom? Give one or more examples of a coelenterate animal. 3. Give (qualitatively) the composition of cellulose, and adduce from the animal kingdom some instance to show that cellulose is not as formerly supposed, exclusively confined to plants.—Botany: 4. Mention any instance known to you in the life-history of a plant which illustrates the law of Alternation of Generations. 5. What are the principal substances which may be deposited in the walls of the vegetable cell so as to give it rigidity and increase its power of resisting organic decomposition? Cite some instances of plants in which cells so constituted occur. 6. Refer to its natural order a plant with the following characters, and give one or more examples:—Leaves alternate without stipules; calyx formed of two sepals which are caducous; corolla with four petals; stamens numerous, inserted on the receptacle; fruit a single-celled capsule with parietal placentæ; seeds numerous, with oily albumen.—Physics: 7. Explain the formation of dew. 8. State the evidence on which we affirm the former existence of glaciers in places where they are no longer to be found. 9. What is meant by the "Torricellian vacuum?" On what physical properties does the existence of this vacuum depend?

Anatomy and Physiology.—1. Describe the inferior maxillary bone, giving an account of the muscles, ligaments, and other parts of importance connected with it. 2. Describe the origin, course, distribution, and functions of the musculo-spiral nerve. 3. Describe the structure, anatomical relations, and functions of the large intestine. 4. Describe the origin, distribution, and communications of the portal vein; give an account also of the character and composition of the blood contained in it, and the office it performs in the animal economy. 5. Describe the structure, anatomical relations, and connexions of the peritoneum.

Medicine.—1. A case submitted for analysis and commentary. 2. Write what you know regarding the composition, mode of origin, the effects, the symptoms, and treatment of gall-stones and bile concretions. 3. Name the common intestinal worms found in man. State what you know as to how each of the parasites you name gets access to the body of man; the symptoms of the presence of each; and the treatment, curative and prophylactic, of each of them. 4. Write what you know regarding the differential diagnosis of facial-nerve paralysis. (Bell's Paralysis.) 5. Name the official preparations in the British Pharmacopœia which contain arsenious acid. State the amount of arsenic in each; and the doses of each. Describe the action of arsenic; and the symptoms which follow its use in extreme doses.

Chemistry.—1. Organic food substances may be divided into two classes—the nitrogenous and the non-nitrogenous. Give some examples of each of these classes. 2. What is the result of heating ammonium chloride with quicklime? Write down the equation which expresses the reactions in this process. 3. Write down in their order the formulæ of the series forming the marsh gas series, beginning with that of marsh gas and carrying it as far as five terms. Give in a formula the quantity by which each term of the series differs from its predecessor.

Surgery.—1. Describe the relative symptoms by which dislocation of the head of the femur, on the dorsum of the ilium, may be diagnosed from dislocation into the sciatic notch. Also describe the measures requisite to reduce each dislocation. 2. By what symptoms may an impacted fracture of the neck of the femur be diagnosed from either of the above-named dislocations? What treatment is best in such an injury? 3. What are the most common causes of inflammation of veins? Describe the effects of such inflammation when implicating one of the lower limbs; and the treatment to be pursued under its various stages. 4. Given a case of stone in the bladder. State under what conditions and circumstances would the operation of crushing—the lateral operation—or the supra pubic operation be preferable. 5. A man has a hard chancre of three or four weeks' duration. What treatment should be adopted in such a case? What are the probable results as regards secondary or tertiary, complications? And, provided the patient is unmarried, what advice should be given as regards matrimony? 6. Describe the preliminary symptoms and subsequent progress of a case of senile gangrene. To what arterial changes is this form of gangrene generally due? And what is the best treatment to be adopted in the progress of such a case?

Brigade-Surgeon-Lieutenant-Colonel F. Howard has been appointed Principal Medical Officer, Belfast District.

ARMY MEDICAL STAFF.—Surgeon-Lieutenant-Colonel R. Drury has assumed charge of the Curragh Station Hospital; Surgeon-Captain W. E Hardy has been posted to the Station Hospital, Colchester; Surgeon-Captain M. O'Halloran has been transferred from Dover to Shorncliffe; Surgeon-Captain H. M. Sloggett has been posted to the Station Hospital, Gosport; Brigade-Surgeon-Lieutenant-Colonel C. A. Atkins has temporarily assumed the duties of Principal Medical Officer of the Western District, vice Surgeon-Colonel J. B. Hamilton, on leave; Brigade Surgeon-Lieutenant-Colonel Robert Collins, M B, is placed on retired pay (dated Feb. 14th, 1892)

NAVAL MEDICAL SERVICE.—The following appointments have been made at the Admiralty:—Staff Surgeons: Edward Ferguson to the *Iron Duke*, and James O'B Williams, M.D., to the *Assistance*, temporarily (both dated Feb. 25th, 1892). Surgeons: Matthew J. O'Regan, M B., to the *Leander*, and Vidal G. Thorpe to the *Peacock* (both dated Feb. 25th, 1892); Edmund Corcoran to Bermuda Hospital, and James M. Rogers to Portsmouth Yard (both dated Feb. 22nd. 1892); Henry B. Beatty to the *Impregnable* (dated March 13th, 1892). Surgeon and Agent: Joseph E. Finegan, at Carlingford, Omeath, Greenore, and Giles Quay (dated Feb. 20th, 1892).

VOLUNTEER CORPS.—*Artillery:* 2nd East Riding of Yorkshire (Western Division, Royal Artillery): Albert Wilson, Gent., to be Surgeon-Lieutenant (dated Feb. 20th, 1892) —*Rifle:* Galloway: Norman James McKie, M.B., to be Surgeon-Lieutenant (dated Feb. 20th, 1892).—1st Volunteer Battalion, the East Lancashire Regiment: Surgeon-Major W. G. Court to be Surgeon-Lieutenant-Colonel (dated Feb 20th, 1892).—3rd Volunteer Battalion, the East Surrey Regiment: Surgeon-Captain W. A. F. Bateman to be Surgeon-Major (dated Feb. 20th, 1892).—1st Nottinghamshire (Robin Hood): Surgeon-Lieutenant L. W. Marshall, M.D., resigns his commission (dated Feb. 20th, 1892).

Correspondence.

"Audi alteram partem."

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS: STEELE *v.* SAVORY.

To the Editors of THE LANCET.

SIRS,—It will be in the recollection of the readers of THE LANCET that in February, 1889, the Association of Members of the Royal College of Surgeons, acting under legal advice and through their committee, issued notices convening a meeting to be held at the College of Surgeons for the purpose of considering the situation of the Members of the College, and approving a draft Bill to be submitted to Parliament, providing for the reform of the constitution of the College. Upon the appearance of these notices the College authorities at once informed the secretaries of the Association that this meeting would not be permitted, and threatened them with the infliction of the penalties under By-law xvii. of the College. The Council furthermore intimated its intention to enforce penalties against each one of the body of Members who might attend such meeting. Nevertheless, the Members assembled, and, finding the doors of the College barred against them, at once adjourned to the Holborn Restaurant, and, acting under the advice of counsel, instructed their secretaries to take Chancery proceedings (Steele *v.* Savory) against the President and Council for the purpose of preventing an immediate enforcement of this oppressive by-law, and testing the validity of the same as to its legality or otherwise, and also for the purpose of asserting the ancient rights of the Members. The action was a "representative" one—that is to say, the secretaries and two other gentlemen who afterwards joined with them became plaintiffs on behalf of the Members of the College generally. The committee being advised by counsel that the action had every prospect of success, and acting at all times on the advice of their solicitor and counsel, the case proceeded. The result of the action is now widely known.[1] By the judgment of Mr. Justice Romer, By-law xvii., and indeed all other by-laws, were declared to be legal so long as they were made in accordance with the terms of the various charters under which the Council of the College claim authority to act. The suit therefore failed, and was dismissed with costs against the plaintiffs. Therefore a special committee has since been formed for the purpose of considering the position of the Association of Members and obtaining the means of meeting the liabilities incurred by the secretaries and members of the committee who were made parties to the suit.

The question of an appeal against the judgment of Mr. Justice Romer was proposed and carefully considered, and

1 See THE LANCET, Jan. 30th, 1892.

Digitized by Google

after weighing counsel's opinion the committee determined that no further legal action should be taken. The eminent counsel consulted pointed out that "the valicity of the power of expulsion does not prevent the by-law complained of being questioned in so far as it purports to impose restrictions upon meetings and discussions, and that the voluminous evidence collected by the plaintiffs shows the existence, in early times at all events, of the rights of the commonalty to be summoned to meet from time to time, and, when so met, of freely discussing all matters concerning the common craft." Counsel further expressed the opinion "that the evidence, however, tends to grow less distinct as time goes on, and that it is questionable whether these rights, though never in terms taken away, had not suffered largely from general encroachments by the governing body and fallen by lapse of time into disuse."

It is now the duty of the special committee to point out that the expenses of the action at law must be promptly met, so that the four nominal plaintiffs—Messrs. Warwick C. Steele, Wm. Ashton Ellis, Jabez Hogg, and W. G. Dickinson—may be speedily relieved from the responsible position in which the adverse judgment of Mr. Justice Romer places them. The committee, on behalf of the whole body of Members, fully realise and share the plaintiffs' responsibility, and, moreover, consider also that they have a strong moral claim upon the Members of the College generally, and they look with perfect confidence for a willing and substantial response to this appeal.

The exact amount of the costs has not yet been ascertained, but if the President and Council of the College press for their costs, then the committee have reason to believe that the whole will not be less than £2000. Be this as it may, the Members of the College will, we feel assured, not allow the plaintiffs to suffer, but by generous assistance testify to their courage and self-abnegation displayed in the important contest in which they have been engaged on their behalf.—Signed, on behalf of the Special Committee, GEO. DANFORD THOMAS,

Feb. 22nd, 1892. Chairman and Treasurer.

Subscriptions may either be sent direct to Dr. G. Danford Thomas, Park Lodge, Paddington, W., or to the National Bank, Bayswater Branch, W. (Steele *v.* Savory Fund).

DR. ROOSA'S TREATISE ON DISEASES OF THE EAR.

To the Editors of THE LANCET.

SIRS,—I crave permission to make a few remarks on your able review in THE LANCET of Feb. 20th on Dr. St. John Roosa's equally excellent book on "Diseases of the Ear." Your reviewer, no less than the author, has done good service in calling attention to "conclusions which are fearlessly stated," and which, when I read them, appeared to me almost as an echo of opinions which you permitted me to express in THE LANCET of July 6th, 1889, and April 11th, 1891. If the echoes of your reviewer are re-echoed by your journal from time to time until they reverberate sufficiently to reach the ears of the medical profession, and through their influence the ears of the public, you will, as you have been on former occasions, be the means of exposing and checking abuses that are harmful alike to the profession and the public. On the subject of electricity (*vide* review) the author in this edition omits certain paragraphs upon the value of electricity as a diagnostic agent, "which he now frankly confesses have not sufficient basis to be of practical utility." Now (*vide* THE LANCET, April 11th, 1891), "perhaps because tinnitus, due to degeneration and some other causes, is of a constant character, the kind of electricity which finds favour amongst its advocates is the constant current; but whether this or the interrupted is employed, it is generally the personally conducted and continuous as long as possible." Whether for diagnostic or curative purposes, the results are practically the same; so there is no advantage on dwelling upon the different reasons which prompt its employment.

Again (*vide* review): "He also gives us a plain opinion on the value of operations upon the tympanic membrane and ossicles in non-suppurative affections of the middle ear, and plainly hints at their experimental nature and generally disappointing results." Now, on incision of the tympanic membrane, with division of the tensor tympani (*vide* THE LANCET, July 6th, 1889): "Its history includes a flight of the imagination, a brief notoriety, and a burial in oblivion so rapid as falls to the lot of few achievements in surgery." Again (*vide* review): "Dr. Roosa speaks in condemnation of operations upon the nose in cases of deafness, and he shares in the opinion of some others that those who now enthusiastically adopt and advise these operations will in time relinquish them." Now (*vide* THE LANCET, April 11th, 1891), on removal of the middle turbinated bone: "As a surgical procedure this operation is outside the pale of serious discussion, and I mention it only as an example of a bubble remedy, that the very mention of it may possibly hasten its inevitable bursting."

I have not as yet had the opportunity of seeing this edition of Dr. Roosa's book, though I am familiar with previous editions, but I hope that he may have echoed what I have said on the subjects of so-called artificial ear-drums and the injections of pilocarpine. On the former (*vide* THE LANCET, April 11th, 1891): "Now practically any form of artificial membrane that is advocated presupposes that all perforations which require protection and pressure can have them usefully applied by one form, the fact being that each perforation requires management, to be acquired only by experience, after careful examination, and when any support of the kind is wanted it must be regulated by the patient, his sensations being the guide in regard to pressure." On the subject of injections of pilocarpine, which were some time ago revived in this country, I say nothing. Professor Politzer, who made the original experiments in 1879, disposed effectually of them in THE LANCET of Jan. 3rd, when he spoke of "practitioners who subject their patients to a long and wearisome course of treatment with pilocarpine," and added: "I feel it my duty to say that they are not too conscientious in the discharge of their calling" You will, Sirs, I feel sure, forgive me for occupying so much space in repeating, and so accentuating, these various points, when you reflect, as I hope you will be able to do ere long, that your journal has been mainly instrumental in putting limits at least, if not a full stop, to the employment of some useless remedies.

I am, Sirs, your obedient servant,

Savile-row, W., Feb. 22nd, 1892. W. B. DALBY.

LARYNGEAL AFFECTIONS AFTER INFLUENZA.

To the Editors of THE LANCET.

SIRS,—During an attack of influenza all the effects of catarrhal inflammation may be observed. Most of these effects are so frequently seen as to be familiar to all. There are, however, complications and sequelæ which are less common. Some patients have been attacked with œdema, coming on in some cases suddenly, in others insidiously. Hæmorrhages from the larynx have been more common and generally very slight. During convalescence ecchymoses and purpuric spots have been observed. Venous congestion, a rare affection in this locality, has been noticed. But the most interesting consequences are neuroses. The paralyses which may be seen in catarrhal laryngitis of course form the larger proportion of these neuroses; but this note is intended to draw attention to the sequelæ rather than the complications of influenza. Paralysis commencing in the throat after convalescence and extending to other regions has so precisely simulated that which follows diphtheria as to suggest a doubt as to the nature of the original attack. But other paralyses, more localised, have also come on after the patients had returned to their avocations. The most commonly affected muscles have been the crico-thyroidei laterales, the thyro-arytænoidei externi et interni, and the arytænoideus. Thus we get more or less paralysis of adduction, either single or double, with corresponding loss of voice. Almost as frequently the action of the thyro-arytænoidei interni and the crico-arytænoidei and crico-thyroidei is impaired or abolished; and as the last named is affected by the superior laryngeal nerve, neuroses of sensation as well as motility result. Anæsthesia and hyperæsthesia of the larynx have also been observed, but the extensive range of normal sensibility in different persons renders it difficult to demonstrate minor degrees of such deviations. Neuralgia is rare, and I have only met with one case following an attack of the present epidemic. I may mention among sequelæ setting in very late choreic movements and spasmodic affections, as well as the stammering of the vocal cords described by me in THE LANCET of Nov. 15th, 1879. These cases are rare. It would appear that these cases of late sequelæ are indications that the effects of influenza remain for a considerable period, and the proportion of

Digitized by Google

neuroses shows how profoundly the disease affects the nervous system.—I am, Sirs, yours truly,

PROSSER JAMES, M.D.

Deanery-street, Park-lane, Feb. 22nd, 1892.

FEES FOR NOTIFICATION.

To the Editors of THE LANCET.

SIRS,—Having had lately several inquiries as to the result of the appeal in the case of Chisholm *v.* Radcliffe Local board, in which I successfully contended that medical men are by law bound to receive the fee of two shillings and sixpence intact for each notification under the Infectious Diseases Notification Act, 1890, and as others besides my correspondents may desire the same information, I am glad to be able to inform all whom it may concern that the fees, with costs, were paid in full and no appeal attempted. Consequently, according to Judge Jones's decision, unless the local authorities arrange otherwise, and thus save double postage, medical men can send the notices in unstamped envelopes, and the medical officer is bound to receive them. Should the local authority attempt to deduct the postage from the bill, as they are ill advised by the Local Government Board to do, they can be sued at court for the full fee; but, if the notices be foolishly prepaid, the stamps cannot be sued for, unless, as I have just said, the authority agreed beforehand to pay. Should the medical officer of health, or such officer as the notice be addressed to, refuse to receive the letter, as was done in my case, it is returned to the sender, who should receive it and pay whatever postage is charged, as it will be evidence, should the case come to trial, that he has done the work for which he claims his fee, and in this instance the out-of-pocket stamp value for the returned notice. I am advised that, should any person be so inclined, any local authority refusing to accept delivery of a notice under the Infectious Diseases Notification Act, 1890, whether prepaid or not, is liable to an action at law for ignoring the notice, and thus endangering the health and lives of the community. It is evident, therefore, that for the present, and until the Act is altered, they are on the horns of a dilemma, and medical men are idiotic who put their hands into their own pockets for stamps, to save the rates, when by law they are exempted.—I am, Sirs, yours truly,

KENNETH MACKENZIE CHISHOLM, M.D.

Radcliffe, near Manchester, Feb. 22nd, 1892.

THE DOVER SANITARY AUTHORITY AND INFLUENZA.

To the Editors of THE LANCET.

SIRS,—In your review of a pamphlet issued by Dr. Sisley I see you refer to the action of the Dover Town Council in a way calculated to convey an erroneous impression as to the notice issued by the above-named authority. Allow me to say that this notice was not an empty threat, but was framed and circulated as an educational instrument with two specific objects in view—viz., first, to declare the fact, now pretty clearly established, that influenza is a dangerous infectious disease; and, secondly, to remind people that the Public Health Act of 1875 provides a method for dealing with persons who, whilst suffering from a dangerous infectious disease, wilfully expose themselves in public places &c. If no proceedings have hitherto followed the notice in question it is not because the Dover Sanitary Authority has been indulging in a farce, but because no clear case has arisen in which a prosecution could be instituted. Suffice it to add that we believe the notice has not only been of great service, but has answered the purpose for which it was issued, and, further, that the course taken has been so far appreciated that it has been followed by many other sanitary authorities.—I am, Sirs, yours faithfully,

M. K. ROBINSON, M.D.,

Dover, Feb. 22nd, 1892. Medical Officer of Health for East Kent.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

A SPECIAL MEETING of the governors of this institution was held on the 22nd inst., for the purpose of considering certain alterations in the laws affecting the honorary medical and surgical staff. Hitherto the terms governing these appointments have heretofore precluded the holding of any office at other hospitals, except those on the consulting staff. It is proposed to do away with this restriction, so that the holders of appointments at the General Hospital may be eligible for other hospitals, and also that any officer on the staff of other hospitals may be attached to the General Hospital when a vacancy occurs. The removal of this barrier is in keeping with modern ideas, and also places the hospitals of the city on the same level with regard to professional appointments being held simultaneously. The alteration is rendered the more desirable since the staff of the workhouse infirmary can be selected from a wider field, and choice made of candidates engaged in duties of a similar kind at the largest hospitals. The other important alteration is that of the honorary medical and surgical staff each member shall be elected for fifteen years, and shall only once be eligible for re-election for a further term of ten years, but he shall not be eligible for re-election if, being a medical officer, he is sixty-five years of age, or a surgical officer, he is sixty years of age, and he shall vacate office on attaining that age. None of the officers, honorary or assistant, shall hold any other office which interferes with the efficient discharge of his duties at the hospital. These, with some minor details, commend themselves on the ground of progress and justice, and no doubt will be ratified at the subsequent meeting to be held shortly.

The Llandudno Convalescent Home.

This home is to be opened on May 7th, so the Hospital Saturday delegates were informed at a social meeting held on the 23rd inst. It was stated also that a magazine was about to be started in support of the Hospital Saturday movement. The premises at Tyn-y-Coed were about to be furnished, some stock had been taken over, and the prospects were bright for the future working of the estate. The promoters of this valuable movement may be congratulated upon the near approach of success to their efforts.

The General Dispensary.

Alderman Clayton presided at the annual meeting held on the 24th inst. The report stated that the income for the year had been £7839 17*s*, while a balance of £356 11*s*. 5*d*. had been carried forward. The total number of patients admitted during the year by tickets had been 29,534, an increase of 3504 over the previous year. The average cost of patients was 3*s*. 6¾*d*., as against 3*s*. 11¾d. Teeth and accident cases had also been 3935. The amount of £1151 2*s*. 2*d*. was acknowledged from the Hospital Saturday Fund. There had been an overdraft of £71 9*s*. 8*d*. on the relief fund, which was a matter of regret, as it crippled the medical officer's work. After some discussion about the tickets, the usual votes of thanks were passed.

Feb. 25th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Influenza and the Death-rate.

CASES of influenza have become less frequent of late, and the death-rate has fallen to a ratio nearer the normal one. Still one hears of professional and lay friends being down with the disease, which has been prevalent here as elsewhere, and the fatalities of the winter from it, its accompaniments, and from other causes incidental to severe weather, have been grievously numerous. The gaps which have been made in the ranks of old citizens exceed those made by any previous winter.

Presentation to a Local Coroner.

Allusion was made in a previous letter to the fact that Mr. Henry Churton, the medical coroner for the Chester district of the county of Cheshire, and for the borough of Birkenhead, had completed his fiftieth year of office as coroner. Mr. Churton was appointed in 1841, when Birkenhead, Crewe, and other important centres with large populations were villages. He was then twenty-eight; hence he has now attained his seventy-eighth year, and still possesses excellent health. He had lately the misfortune to suffer a severe bereavement in the death of his wife. Advantage was recently taken by some residents at Birkenhead to present him with a silver bowl as a token of the esteem in which he was held in that town. In return-

ing thanks, Mr. Churton said that, though he had been urged by some friends to retire, he hoped to be able to perform his duties for some time to come.

The Hospitals and their Friends

The annual meetings of all the hospitals have been held now. Special appeals on behalf of the Stanley and of the Royal Southern Hospitals had recently to be made, and the response was very generous. It can hardly be said that four general hospitals are too many for such a city as Liverpool, nor that they are out of proportion to those in other cities and towns, taking the aggregate number of beds. The difficulty here has always been that in so modern a city as this the oldest charities have not the liberal endowments of more ancient cities, and are almost entirely dependent upon annual subscribers, the Hospital Sunday and Saturday Funds, donations and legacies, which latter have to be expended, instead of being invested as could be wished. Citizens who have subscribed for many years are removed by death, and their places are not filled by new subscribers in equal proportion. Meanwhile the work done by the hospitals continues to be as heavy as, even more so than, previously.

Feb. 24th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Fleming Memorial Children's Hospital.

THE annual meeting of the Newcastle Children's Hospital has been held. This fine and very commodious building was erected by the late Mr. Fleming, solicitor, of this city, as a memorial of his wife. The number of in-patients treated has been 431, being an increase of 200 over the previous year; while the number of operations performed has risen from 53 to 137. As regards the financial position of the hospital, it was not so satisfactory. The increased work had caused a loss on the year's working of about £600. It was explained that, unless more public support was given to the institution, some of the beds would have to be closed; but, from the signs of fresh efforts and donations promised, I think this is unlikely to occur. If the working men of the north were roused, they could keep up this (and any other medical charity here), which has been established principally for their benefit.

Newcastle Health Society.

The second lecture of the course promoted by the Newcastle Health Society has been delivered on the Eye by Mr. G. E. Williamson, F.R.C.S., honorary surgeon to, and surgeon of, the eye department, Newcastle Royal Infirmary. The lecture was well received and fully illustrated, as also the lecture which followed by Dr. Drummond, physician to the Royal Infirmary, on the Brain. All these lectures have been very well attended.

Our Handwriting and "Ourselves as others see us."

A writer in one of our daily papers, on the question of handwriting, says that "doctors are very clever men, but they are subject to fads, and they are very fond of writing about things they do not understand." He asks: "Now, what do doctors know about handwriting? Can any living being except a chemist decipher their scrawls?" He further says that sloped writing is natural, as may be seen if anyone will sit down and try to make straight strokes they will slope to the right, and if made with the left hand they will be found to slope in the contrary direction, which he thinks proves that sloped writing is natural.

Alnwick: High Death-rate.

At the last meeting of the Alnwick Board of Health the medical officer, Dr. Easton, presented his report, which showed that during the month of January the number of deaths rose to 33, and that this was principally caused by diseases of the respiratory organs. This excessive death-rate was equal to an annual mortality of 50·18 per 1000 of the population. At ordinary times the death-rate of the town is not at all high.

Darlington Hospital.

The annual report of the Darlington Hospital, presented at the meeting last week, shows that 109 patients had been admitted last year. There were twelve deaths, a percentage of 6·41. The operations numbered sixty-one. The work of the out-patients' department showed a considerable increase, in great part attributable to influenza; 4047 out-patients' tickets were brought to the dispensary, and 1120 patients were attended at their own homes. The number of visits paid was 9118. The financial statement was satisfactory, leaving a balance of £211 with the treasurer.

Weardale and Teesdale.

The Weardale Lead Company write to the sanitary authority stating that they have put up in their mine shops the authority's notice with respect to the overcrowding of mine shops, remote places where workmen miles from home sleep during the week. The company also intimate that they have asked their men to avoid further complaint. The authority, however, take the position that responsibility for continuance of the cause of complaint will still rest with the company. The Teesdale medical officer, in his annual report to the sanitary authority, says that the great falling off in the dale population is entirely owing to the low wages and want of employment, obliging young men to seek employment in other places.

Carlisle.

The annual meeting of the Cumberland Infirmary at Carlisle has been held, the report showing that 750 in-patients had been received during the year. The death-rate for the year has been very high, standing at 7·3 per cent. The financial statement was satisfactory, showing a small increase of subscriptions received over those of the previous year. £386 had been collected by the Ladies' Association, and £624 from Hospital Sunday Fund and collections in churches, being a little over the ten years' average. There had been a small reduction in the cost of maintenance of patients. The committee recommend that the sum of £1000 received under the will of Miss Thomason Nelson of Moor-row should be applied to the current account, subject to the sanction of the governors. The annual meeting of the subscribers of the Carlisle Dispensary has also been held. The medical report showed that 3477 cases had been treated at the dispensary during the year; of that number, 1972 were home patients and 1505 out-patients. The mortality showed that of these 96, or 2·7 per cent., died of the complaints treated. Bronchitis stood highest, with an array of 550 cases. During the year an epidemic of measles broke out; 224 cases were entered, and 6 proved fatal. Influenza, after a year's absence, reappeared in May, but was of a mild type; in December it again appeared, 96 cases being registered in that month. It was remarked that 3477 was the largest number remembered as being on the books of the institution in a year.

Stockton: Opening of New Baths.

At Stockton the new baths erected by the corporation were opened by the Mayor last week. The establishment is most complete, comprising slipper, swimming, and Russian vapour baths. The swimming bath is said to be one of the finest in the kingdom, and is provided with forty dressing boxes. This bath is seventy-six feet long by twenty-seven feet wide. The whole cost of the baths has been over £7000. The corporation is to be congratulated on its public spirit and advanced position in sanitation.

Newcastle-on-Tyne, Feb. 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University Court.

AT a meeting of the University Court last week Dr. John Wyllie, Edinburgh, was appointed Additional Examiner in Clinical Medicine for one year from Jan. 1st last. Recognition was also granted to the Public Health Laboratory of the University of Aberdeen as one in which practical instruction is given in the methods of investigating subjects pertaining to public health, which should qualify for graduation in science in the Department of Public Health in the University of Edinburgh; and to Professor Matthew Hay, M.D., Aberdeen, as teacher of public laboratory work in the laboratory.

The Question of Unsound Meat in Edinburgh.

There have from time to time been expressions of dissatisfaction from the butchers as to reports on the seizure of unsound meat in Edinburgh, and the recent case of anthrax appears to have made them still more

Digitized by Google

anxious to have steps taken to put the trade above suspicion. A deputation from the Master Butchers' Association has had an interview with a subcommittee of the Public Health Committee of the Town Council, after which the matter was discussed at length by the whole committee. The proposal involved the establishment of a clearing-house, into which all dead meat should be sent in order to be inspected and certified before being exposed for sale. This suggestion, if carried into effect, and the work of inspection committed to skilled persons, would be as satisfactory a guarantee as could be provided, and would do much to lessen the feeling of uncertainty and insecurity which lingers in the public mind.

The Health of Edinburgh.

The mortality last week was 81, making the death-rate 16 per 1000. Diseases of the chest accounted for at least 40 deaths, and zymotic diseases for 9, of which 4 were due to measles. The intimations for the week comprised: typhus fever 1, typhoid fever 1, diphtheria 9, scarlatina 12, and measles 78.

Scottish Microscopical Society.

At the meeting of this society last week, Mr. Gustav Mann made an interesting and elaborate communication on the Phenomena of Fertilisation in the Embryo Sac of Flowering Plants, which he illustrated by means of diagrams and numerous microscopical sections. Dr. Joseph Coats of Glasgow read a paper on the Pathology of Sudamina, which he illustrated by means of a microscopical demonstration. After reviewing the present position of our knowledge on the subject and the various views held, he contended that the sudamina were the result of blocking of the sweat glands, and the condition was accompanied with leucocyte migration, and was an irritative or inflammatory one. Mr. George Brook, lecturer on embryology in the University, made a communication on some recent researches on "direct" or Amitotic Nuclear Division, which, however, he was unable to finish owing to the time occupied by the other papers.

The Edinburgh Association for the Reform of Medical Education.

This Association has prepared and presented a second statement to the Universities Commissioners on Draft Ordinance No. 10 (General) The statement refers to the duties and emoluments of professors, lecturers, and assistants.

Feb. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Royal University of Ireland.

AT a meeting of the Senate last week several Fellows were appointed, some reappointed, and examiners selected for the ensuing year. Drs. Ambrose Birmingham and W. Thornley Stoker were appointed Medical Fellows.

British Medical Association: Dublin Branch.

The fifteenth annual meeting was held last week in the Royal College of Physicians, presided over by Dr. Walter G. Smith. The members dined in the College in the evening. The President for next year will be Dr. Arthur Foot, senior physician to the Meath Hospital.

Poor-law Officers.

A deputation from the various Irish associations interested in the matter waited on the Vice-President of the Local Government Board with reference to the question of superannuation, and urged the necessity of having the Union Officers' Superannuation Bill of 1884 passed into law. Mr. Morris promised that their views should be laid before the Government, and that he would do all in his power to redress the grievances of Irish Poor-law officers.

Proposed Hospital for Consumption.

A meeting was held last week at the Royal College of Physicians for the purpose of establishing a hospital for phthisical patients in the neighbourhood of Dublin. Dr. Finny, President of the College, occupied the chair, and stated that his Excellency the Lord-Lieutenant had promised to contribute £500 provided that the sum of £10,000—which the committee considered necessary before starting the institution—was subscribed within six months, while the Countess of Zetland had collected a sum of £1500. The object of the committee, he said, was that the hospital should be non-sectarian, that it should be a place where the poor might find for themselves a home where they would have pure air. The Registrar-General believed that the institution was necessary, because the disease was infective and could not be treated in ordinary hospitals. Considered as a single disease, it was the most potent cause of death in Ireland, more than one-tenth of the deaths registered in Ireland between 1871 and 1880 being due to it. The building would cost probably £2000, and about £5000 a year for maintenance.

Dublin Main Drainage.

Mr. Cotton, chief engineering inspector of the Local Government Board, held an inquiry last week, in the City Hall, in reference to the application made by the Corporation of Dublin to obtain the sanction of the Board for obtaining loans amounting to £278,000 for the purpose of carrying out the proposed main drainage scheme for the city. The Lord Mayor, who was examined, stated that the scheme, which had been unanimously adopted by the Corporation, consisted of an intercepting sewer from Kingsbridge on the north side to Marlborough-street, and to a place on Burgh Quay. There was also a sewer provided for Kilmainham, and another for Island Bridge, joining the sewer at Kingsbridge; while a syphon under the Liffey joins the north and south systems. Ultimately the sewage is discharged into the outfall, running along parallel to the Pembroke and Rathmines main outfall sewer, round the Pigeon House Fort to the White Bank, where the precipitation tanks are. At the White Bank the sewage would be stored in tanks, and chemically treated. The solid sludge would fall to the bottom, leaving the clarified effluent, which would be precipitated into the river in a harmless condition. The solid matter would be pumped into a steam barge, and then carried out to sea. The sewers will be constructed of Portland cement concrete, with an internal ring of four inches and a half of brickwork laid in Dublin cement. Mr. Chatterton of London is the sanitary engineer, and there is no reason to doubt that the proposed scheme will be sanctioned by the Local Government Board. The cost of repayment will be about 8*d.* in the pound on the valuation.

The late Mr. N. C. Whyte, M.R.C.S.

The late coroner for Dublin, Mr. Whyte, died without leaving any means for his widow and daughter, and a fund has been started for the support of the widow, her daughter having died within the last few days. Although Mr. Whyte drew a salary of £500 yearly, yet he was a man of great benevolence, and subscribed largely to various charitable objects, and, his health being delicate, he was unable to insure his life.

Coroner for South Kilkenny.

There were four candidates for the vacant coronership, three of whom were medical practitioners. The voting was as follows:—Dr. Walsh, 877; Dr. Stephenson, 830; Mr. J. J. Shee, 508; and Dr. F. E. Cane, 314.

Cork Union: Election of a Medical Officer.

By the death of Dr. Crowley a vacancy for a dispensary medical officer had arisen, and this week a meeting of the dispensary committee took place to elect a successor. There were six candidates, three of whom withdrew, and finally Dr. O'Mahony was elected by a majority of votes.

The Lord-Lieutenant has appointed Patrick W. Maxwell, M.D., to be Surgeon Aurist in Ordinary to his household.

Surgeon-General Samuel B. Roe, C.B., of Ballyconnel House, has been appointed sheriff for the county of Cavan.

Feb. 23rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Novel Treatment of Neurasthenia.

HYPODERMIC THERAPEUTICS continue to grow in favour. This applies not only to the chemical substances of the Pharmacopœia, the hypodermic administration of which has in recent years so much extended and is now firmly established, but bids fair to take a new departure on the lines advocated by Brown-Séquard. In this latter connexion M. Constantin Paul, at a recent meeting of the Academy of Medicine, related his observations of a certain number of cases which he had treated by injections of a preparation of nervous substances into the subcutaneous cellular tissues.

Digitized by Google

The patients over whom his observations of this novel therapeutic method extended numbered eleven, which he classified as three of chlorotic neurasthenia, three of classic neurasthenia, one case of permanently slow pulse, and four ataxics. The liquid used was a solution of 1 in 10 of cerebral grey matter taken from the sheep, sterilised by carbonic acid in Arsonval's apparatus. This solution was injected in the gluteal region, the dose being 5 cc. It was well borne, producing no reaction, either local or general. Occasionally a slight lymphatic engorgement was noticed, which disappeared in four or five days; but in the two hundred injections to which the eleven patients were subjected in no case was there abscess or other local inflammation. The first sensation experienced by the patients was one of comfort and returning strength, the previous muscular weakness diminishing sensibly. The vertebral pains and spinal hyperæsthesia, and, in the case of the tabetics, the lightning pains, disappeared gradually. Appetite for food also came back, and those of the patients who were previously dyspeptic now assimilated their food so well that they began to increase in weight. In the ataxics sexual power returned with the general amelioration. M. Paul concludes from these considerations that in injections of grey cerebral matter we have a nervine tonic of no mean order. He compares a neurasthenic with an accumulator which it is impossible to charge; while the condition lasts he is unable to transform his food into force. After the least effort his muscular and intellectual forces are exhausted. But the injection of nervous matter in the manner indicated promotes the utilisation of food and its due assimilation; so that the nervous system now becomes a condenser, which, if charged, the subject acquires force which he can dispose of at will. It is to be noted that it is the nervous force which first returns in all these cases. Following this, and as a consequence, the power to do intellectual and muscular labour comes back; the improvement in the condition of the blood follows later on. In conclusion, M. Paul expresses his conviction that this new therapeutic departure will be found to ameliorate the neurasthenic condition much more rapidly than the methods of our ordinary materia medica—an opinion which strikes one as being rather sanguine.

Rickets a Parasitic Disease.

To the list of ills to which our humanity is the inevitable but unwilling heir owning a microbic origin must, according to Mercoli, now be added rickets. This observer has already, he submits, in a series of anterior researches, traced sciatica, chorea, and hydrocephalus to their microbic sources. Continuing his investigations in the cases of children dead of hydrocephalus and rickets, he confirmed his previous conclusions, and has, moreover, he affirms, succeeded, after examining and submitting to bacteriological methods the costal nodes peculiar to rickets, in obtaining pure cultures of a specific microbe. In adults, according to this observer, the micro-organism of rickets produces merely local symptoms; but, in the case of young children unaccustomed to the presence of these microbes, the affection is at first general, finally localising itself where functional and formative activity is most intense—viz., in the osseous and nervous systems.

The Function of the Supra-renal Bodies.

According to MM. Langlois and Abelons, who, at a recent meeting of the Biological Society, brought forward the results of their further researches on the function of these physiologically little known organs, the destruction of one supra-renal body does not entail death, while the removal of both invariably does, accompanied by all the phenomena described by Brown-Séquard, paralysis of the respiratory muscles, &c. This paralysis they found to affect the terminal nerve plates in the muscles. At the moment of death, and a little before, the sciatic and phrenic are absolutely inexcitable, although the muscles supplied by these nerves in part respond to stimulation. The blood of guinea-pigs on which the observations were made caused, when injected under the skin of the frog, phenomena analogous to curarisation, and MM. Langlois and Abelons incline to the belief that a chief function of the supra-renal capsules is to destroy or neutralise some such poisonous substance engendered by the organism.

French Congress of Surgery.

The Surgical Congress of 1892 will be opened in Paris at the Faculty of Medicine on Monday, April 18th, under the presidency of Professor Demons of Bordeaux. The first sitting will be held at 9 A.M., and is to be devoted to the discussion of general questions, but the formal inauguration of the Congress will take place at 2 P.M. The following questions have been placed on the agenda for discussion: (1) The pathology and treatment of surgical gangrene; (2) the pathology of infectious complications in the surgery of the urinary organs; and (3) surgical operations on the biliary passages, with their immediate and remote results. The morning session will be devoted to general discussion or visits to the surgical wards of the hospitals. Those desirous of taking part in the Congress are requested to forward the title and conclusions of their intended communications to M. Félix Alcan, publisher to the Congress, 108, Boulevard St. Germain, of whom also any inquiries may be made.

Paris, Feb. 24th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Koch.

AT Professor Koch's invitation several representatives of the Government, Surgeon-General von Coler (head of the medical department in the Prussian War Office), many other well-known medical men, and a large number of members of the Prussian House of Deputies, visited the new Institute for Infectious Diseases yesterday. They met in the lecture-hall of the Institute, where Professor Koch delivered an interesting lecture on the aims and labours of the establishment. He alluded especially to the recent researches carried on in the Institute with regard to protective inoculation and the cure of the most dangerous infectious diseases. The lecture was followed by a demonstration of the most important bacteria by means of the large electric projection microscope. Dr. Koch then led his guests through the hospital and the laboratories of the scientific department. The *Post* states that Dr. Koch intended to leave Berlin yesterday evening for Sicily, to spend four weeks there.

A Bacteriological Discovery.

The well-known Japanese bacteriologist, Kitasato, who works in the scientific department of Koch's Institute for Infectious Diseases, has made an important discovery, which he records in the *Zeitschrift für Hygiene*. He has discovered by attempts at cultures from sputa that the great majority of the tubercle bacilli found in sputum are dead, a fact which cannot be proved microscopically, because dead bacilli stain just as rapidly and as intensely as living ones, from which also they do not differ in form. The same is true of preparations made from the contents of vomicæ. This discovery is of considerable importance from its bearing on the diagnostic value of preparations from sputum, and on the question of the transmissibility of pulmonary tuberculosis from one person to another.

Personal Items.

Professor Adolf Kussmaul, one of the most distinguished clinical teachers in Germany, celebrated his seventieth birthday yesterday. He resigned his Strasburg professorship in 1889, and retired to Heidelberg.

The Halle Academy of German Naturalists has conferred the Cothenius Medal on the Anatomist Professor Retzius of Stockholm. This medal was founded in memory of Christian Andreas Cothenius, physician-in-ordinary to Frederick the Great, and Prussian Surgeon-General during the Seven Years' War, who died in 1789.

Dr. Kopp, Professor of Chemistry in the University of Heidelberg, died on the 20th inst.

Dr. Moritz Altmann, a district medical officer, whose name became honourably known more than forty years ago, owing to his zealous activity when famine fever was raging in Upper Silesia in 1848, died the other day.

Influenza.

The number of deaths in Berlin from influenza from the beginning of this winter's epidemic down to the 6th inst. was 544.

It is reported from various parts of Saxony that many dogs have been attacked of late by influenza. The symptoms are complete loss of appetite, aversion to water, inclination to bite, and water in the eyes. The disease is epidemic, and death is not infrequent.

Digitized by Google

London Vigilance Society.

The secretary of the London Vigilance Society was here the other day to deliver to the Emperor William the address, the sending of which was resolved upon at a meeting held under the presidency of the Lord Mayor. The Foreign Secretary, Baron Marschall, who received the address in His Majesty's name, expressed the sympathy with which the latter regards the humane efforts of the Society, and alluded in grateful terms to its action on behalf of German girls living in London.

Berlin, Feb. 23rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Trial of a Medical Student for Alleged Poisoning.

PROFESSIONAL circles of this city have been much interested in the trial of a medical student for the alleged poisoning of his wife. He had clandestinely married, and at the time of his wife's death he was a medical student in one of the colleges of this city, and she was a pupil in one of the most fashionable schools for women. Her sickness was due to an operation which he performed to procure abortion, but her death was attributed to morphine administered by him. He prescribed four grains of quinine and one-sixth of a grain of morphine in capsules, and the theory of the prosecution was that in one capsule he placed a fatal dose of morphine. Suspicion of crime was not excited until several weeks after death, when the body, fifty-three days after burial, was exhumed and an examination made. Morphine was traced, but no evidence of quinine. Experts of the highest rank appeared on both sides. The theory of the defence was that the dead woman either did not die of morphine poisoning, or, if she did, that she was unusually susceptible to its effects owing to diseased kidneys, and one-sixth of a grain proved fatal. The points of scientific interest were: (1) As to the possibility of determining the condition of the kidneys fifty-three days after death; and (2) as to the reliability of the tests for quinine. The first was decided in the negative by an experienced pathologist. As to the second, the prosecution had relied upon the following tests for quinine by Professor Wittans—viz., absence of fluorescence, the bromine experiment, and the absence of bitter taste. Professor Wormley, for the defence, contended that fluorescence is no certain test when it is applied to the chloride of the substance; the failure to obtain a green colour with bromine is not conclusive; and finally, experiments by Koerne show that quinine may be modified in form when it passes through the body, and its bitter taste be lost. The verdict was "Murder in the first degree." The expert testimony was so conflicting as to be entirely ignored.

Increase of Slum Population in Cities.

The United States Commission of the Labour Bureau publishes some interesting facts relating to the increase of population in the congested wards of several cities. In New York the increase in the overcrowded districts was in twenty years 9·38 per cent., while the increase for the whole city was 60·81 per cent. In Philadelphia there has been a loss in the compact wards in twenty years of 6·56 per cent., while other portions of the city show an increase of 68·91 per cent., and the total gain for the whole city was 55·33 per cent. In Boston for ten years the slum population increased 1·04 per cent., while the other parts of the city increased 31·96 per cent. The report shows that the crowded population of our cities is on the whole slowly declining.

Sanitary Inspections at Havana, Cuba.

For several years the United States has maintained a sanitary inspector in the consular office at Havana. During the past year he examined 636 vessels bound to the United States; of these, the sanitary condition of 343 was reported as good, 193 fair, 100 fair only, suspicious, or bad. All the vessels which had yellow fever on board in the harbour lay at the wharves and mostly on the Havana side, thus demonstrating, the inspector says, that the infection is about the wharves and not in the waters of the harbour. The inspector grants health certificates to applicants in accordance with the rules of our quarantines. The certificate sets forth that the recipient is acclimatised to yellow fever either by a previous attack of the disease or by a continuous residence for ten years or more in towns and cities habitually subject to it in an epidemic form, or where it prevails endemically, and by having passed through at least one severe epidemic; the certificate also states that the person is protected from small-pox, and is free from leprosy. To 4569 persons these certificates were granted and to 455 they were refused. The value of these certificates is shown by the fact that not less than 20,000 such certificates have been issued by the inspector, and in no instance has the recipient been subsequently afflicted by either disease. The effect of these sanitary inspections and examinations of vessels, crews, passengers, and baggage, in keeping out contagious fevers, leprosy, and other diseases from the United States, is very great. The influence of the examinations in furthering maritime sanitation and in preventing contagious diseases from invading a vessel is quietly felt all through the harbour of Havana. Captains and owners of vessels bound to the United States keep and put their vessels in better sanitary condition, keep bilges sweeter and cleaner, make efforts to prevent contagious diseases from invading the vessel, and, if once aboard, to get rid of the influence. It is interesting to notice that the inspector has frequent occasion to refuse certificates to persons suffering from leprosy. He states that there are not far from 200 cases in Havana, and it requires constant vigilance on his part to prevent them from emigrating to the States.

New York, Feb. 5th.

Obituary.

THOMAS SYMPSON, F.R.C.S.,

OF LINCOLN.

BY the unexpected death of Mr. Thomas Sympson the city of Lincoln loses one of its best known and most highly esteemed practitioners. His father, Mr. Thomas C. Sympson, also a medical man, was for many years in practice in the same city. Mr. Thomas Sympson, who was born in the year 1825, was an apprentice to his father, and afterwards entered as a student at St. Bartholomew's Hospital, where he gained several prizes. In 1847 he became a member of the Royal College of Surgeons, and was appointed house surgeon to the Lincoln County Hospital, which post he resigned in 1852, and commenced practice in the city of Lincoln. In 1854 he was elected surgeon to the Lincoln County Hospital, and at the time of his death was senior surgeon. He also held the appointments of honorary surgeon to the Lincoln General Dispensary and the Lincoln Asylum, and was at one time surgeon to the city gaol. He became a Fellow of the Royal College of Surgeons in 1872, after examination. Mr. Sympson represented the Midland Branch of the British Medical Association for many years on the Council of the Association, and had held the office of President of the branch. He was also a Vice-President of the Ophthalmological Society. He took great interest in the Lincolnshire Medical Benevolent Society, and was one of the trustees. His knowledge of medical literature was very extensive, and he was well acquainted with the collateral sciences. Known throughout the county as a skilful surgeon and as a successful practitioner, his loss will be severely felt by his brother practitioners, with whom he was ever on good terms; they highly esteemed him as a straightforward, honourable man, and frequently availed themselves of his advice. His loss will also be much regretted by a large circle of friends to whom he was endeared by his many amiable qualities. A day or two before his death he exhibited symptoms of angina pectoris, which proved fatal on the 10th inst. By those who remember the genial presence of Mr. Sympson, the kindness of heart which ruled his conduct towards all, and his devotion to surgery, as exhibited more especially in his untiring work at the Lincoln County Hospital, his memory will never be forgotten, nor will the high standard set by him prove without its value as an encouragement in the struggle of life.

MR. COOKE'S SCHOOL OF ANATOMY, PHYSIOLOGY, &C.—The London University has recently recognised Mr. Thomas Cooke's School of Anatomy and Physiology as a teaching institution. This will enable students who have attended the courses there to enter for the degrees given by that body up to the Intermediate M.B. Examination.

Gabbett, P. C.	3060

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the respective subjects:—

Surgery.—R. Freer, St. Mary's Hospital; A. W. Fyffe, Middlesex Hospital and Belfast; W. C. Hinde, Middlesex Hospital; J. H. Hobling, St. Mary's Hospital; H. F. Ransome, Owens College, Manchester; F. K. Rider, Yorkshire College, Leeds; J. W. Smith, London and Manchester; P. M. Toms, Middlesex Hospital.

Medicine, Forensic Medicine, and Midwifery.—G. H. Baird, St. Mary's Hospital and Dublin; W. T. B. Donelly, Guy's Hospital; W. Overend, St. Bartholomew's Hospital; D. L. Thomas, London Hospital.

Medicine and Midwifery.—G. M. Arkle, Liverpool Royal Infirmary; V. J. R. Robin, King's College; G. P. Smith, Guy's Hospital; A. S. Ware, St. Thomas's Hospital.

Forensic Medicine.—P. J. Naden, Queen's College, Birmingham.

Midwifery.—G. R. S. Breeze, Royal Free Hospital; J. R. Daly, King's College.

To Messrs. Arkle, Baird, Daly, Hinde, Overend, and Miss Breeze was granted the diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery.

MELBOURNE ROYAL COMMISSION. — The Royal Commission now sitting at Melbourne to inquire into the condition of, and the means of improving, the charitable institutions of that city, have had the benefit of listening to the evidence of Dr. Gresswell, who has detailed the advantages to the community of a system of isolation in infectious diseases. He recommends the building of fever hospitals in the Bay. The chief difficulty in Melbourne, as elsewhere, lies in the constitution of the administrative bodies upon whom the efficacy of any sanitary measures largely depends. Dr. Gresswell advises the appointment of a hospital board composed of delegates from the various municipalities interested in the work of the institution.

CANCER HOSPITAL (FREE), BROMPTON, S.W.—The forty-first annual meeting of the governors of this charity was held in the board room of the hospital on the 24th inst., Sir George S. Measom, J.P., chairman. This hospital was founded in 1851 for providing free admission to poor persons suffering from cancer on their own application, and it is satisfactory to notice that the relief afforded increases year by year. The report of the committee showed that during the past year 1788 new patients were received, 682 being in- and 1106 out-patients, whilst the total number of attendances of out-patients was 7498, these figures being in excess of any previous year since the hospital was founded. An earnest appeal is made by the committee for increased support, to enable them to carry on the important work of alleviating, and, as far as possible, arresting, the growth of this terrible disease. The Samaritan Fund for assisting discharged patients had proved very useful, some being sent to convalescent homes, and others receiving pecuniary aid. The medical staff give a course of lectures during the first three months of the year, which are open to all medical practitioners and students. The report and balance sheet were adopted, and the usual votes of thanks accorded.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—His Royal Highness the Duke of Edinburgh presided at the annual meeting held at the institution on the 18th inst. The attendance was unusually large. The report stated that during the year 1891, 1256 patients, including readmissions, had been received into the wards. In the out-patients' department 2076 persons were treated. The long-required additional sleeping accommodation for the nurses had been accomplished, and ten more rooms provided. The total outlay of the additions and other improvements amounted to £869.

THE EXTENSION OF CARDIFF INFIRMARY.—The committee identified with the movement for collecting funds for the extension of the infirmary held a meeting last week at the Hôtel Métropole, Cardiff. Mr. Coleman (secretary to the infirmary) explained the urgent need of additional accommodation. The infirmary was scarcely half large enough to meet the requirements of the town. If £6000 could be collected it would cover the cost of the proposed extension. It was resolved that the time had arrived to extend the accommodation of the infirmary; that a public meeting be held early at the town hall, and that a provisional committee be formed for promoting the object in view.

CHARING-CROSS HOSPITAL.—The annual general Court of Governors was held last week. The report for the past year referred to the offer of Mr. J. Passmore Edwards, who had asked to be allowed to build and furnish, solely at his own expense, a convalescent home, with accommodation for fifty beds. Mr. Edwards had already sent a cheque for £5000, and would provide the remainder of the estimated cost of the home when the foundation stone was laid. The Council, continued the report, were most grateful to Mr. Edwards for his munificent gift, and for expressing the hope that his donation would in no way prevent the flow of the subscriptions. The sum now reached was £6600, being the £5000 from Mr. Edwards and £1600 from other sources. The number of in-patients treated during the year exceeded that of any previous twelve months, and the out-patients numbered 23,539.

FRENCH HOSPITAL AND DISPENSARY.—The twenty-fourth annual dinner on behalf of this institution took place at the Hôtel Métropole, Whitehall Rooms, on Saturday evening last, M. Waddington, the French Ambassador, in the chair, supported by the Lord Mayor and members of the diplomatic body in London. According to the report, which was read by the honorary secretary (M. Ruffer), 731 in-patients and 19,274 out-patients received medical relief during the past year, a number largely in excess of previous years. The consequence of this has necessarily been a corresponding increase in the expenses of maintenance, and a deficit remains, represented by the difference between £3213 and £4039. His Excellency made an urgent appeal to the supporters of the institution to come forward and, by a further measure of assistance, to enable the authorities of the hospital to maintain it in its present condition of efficiency. The usual toasts were proposed and responded to after a touching allusion by his Excellency to the painful circumstances attending the death of the Duke of Clarence, and subscriptions were announced amounting to upwards of £2500.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—According to the statements made recently at the annual general meeting of the Royal South London Ophthalmic Hospital, to be called in future the Royal Eye Hospital, South London will, in the course of the next few months, be in possession of a hospital which, both as regards construction and sanitary arrangements, will vie with the best. The hospital is situated in St. George's Circus, and has been carrying on its work for many years at two shops. A fine building has, however, been erected at a cost of £26,000, and presents some noteworthy features. Among these may be mentioned that the entrance to the hospital is under a covered footway, which obviates the necessity of patients waiting in the rain; another is that a blind patient goes from entrance to consulting room and back again without meeting a single edge or projection of any kind; whilst other noticeable features are, a fine asphalted promenade on the roof, and fire arrangements remarkable alike for safety and completeness. These latter consist of a lift which, extending from roof to basement and having no shaft, cannot be affected by fire or smoke. It is reached by a projecting platform outside each floor.

Digitized by Google

GIFT OF AN ISOLATION HOSPITAL.—The long-felt want of an isolation hospital for the township of Birstall, which adjoins that of Batley, has been provided by the spontaneous offer of Mr. William Robinson, of the Raikes Tower Brewery, and a member of the local board, to give the Volunteer Inn, in Upper Batley Lane, Howden Clough, to be adapted for an infectious hospital. It is in close proximity to the present Batley isolation hospital. The board appreciated and accepted Mr. Robinson's offer.

CITY OF LONDON LYING-IN HOSPITAL.—This excellent charity publishes a special appeal—the only one for twenty years. It shows that 1974 poor women were attended in 1891. The expenditure of the hospital has exceeded its income by over £500. It is alleged that 118 in- and 522 out-patients belonged to the poor of Islington, that they were attended at a cost of over £600, while only £31 was received from that parish in subscriptions and donations. This is an illustration of the fact that most medical charity comes from other districts.

THE SMALL-POX AT BATLEY.—On the occasion of the annual dinner of the Heavy Woollen District Fire Brigade Association, on the 20th inst., the mayor (Alderman Brooke) is stated to have announced that since the outbreak commenced there had been a total of 300 cases, while the deaths numbered 25. He was happy to say that while there had been over 80 houses infected, at the same time there were only now 50 houses so affected—a reduction of 30. There were hopes that the disease would before long be stamped out.

ROYAL NORTHERN SEA-BATHING INFIRMARY.—The past year's report states that the infirmary was open from May 1st until Dec. 12th. In that period 587 patients were admitted. The total income for the year, including £230 brought forward on Jan. 1st last, was £1892 19*s.* 9*d.*, and the disbursements amounted to £1681 4*s.* 10*d.*, an excess of £67 7*s.* 8*d.* over the previous year, accounted for by the extra cost of refurnishing and other necessary outlay. Some additions are to be made at the north end of the infirmary, which will give the accommodation required for the staffs and provide another ward of eight beds for patients.

FUNERAL REFORM.—At a meeting of the Funeral Reform Association, held in the Council Chamber, Halifax, upon the motion of the Archdeacon of Halifax, seconded by the medical officer of health, it was resolved to petition Parliament for improved burial legislation. The Bishop of Marlborough will preside at the third monthly meeting of the Association in the Church House, Westminster, on Thursday, March 3rd, at 4 P.M., when the subjects for consideration will include the means of providing suitable burial-places near populous towns, to be used as quasi-crematoria for the dispersion of the dead by the action of the earth and air, instead of their preservation.

METROPOLITAN HOSPITAL.—The annual meeting was held at the institution, Kingsland-road, last week, Mr. Joseph Fry presiding. The work of the charity had considerably increased during the past year in both the in- and out-patients treated; the total out-patient attendance was 69,196. The receipts show a decrease of £550, and the expenditure an addition of nearly £400, the former being due to the small amount received from legacies, and the latter to the large number of patients treated. Lord Sandhurst, chairman of the Royal Commission on Hospitals, had promised to preside at the festival dinner on behalf of the hospital on June 30th.

TESTIMONIAL TO MR. COLLINS OF DUBLIN.—Visitors to and members of the General Medical Council who are familiar with the kindly, free, and sound judgment of Mr. Collins, the representative of the Apothecaries' Society of Dublin on the General Medical Council, will be gratified by a little incident recorded as a public notice in the *Irish Times*. "Mr. Collins, for the long period of thirty-three years, has filled the office of one of the honorary secretaries of the Old Men's Asylum, Northbrook-road, Dublin. His colleagues desire to testify their sense of the high value of his services and those of Miss Collins, and attribute largely to them the prosperous state of the institution and its finances." We congratulate Mr. and Miss Collins on this work, so pleasant in retrospect, and so well appreciated by those best able to judge.

BRADFORD EYE AND EAR HOSPITAL.—The thirty-fifth annual meeting of the subscribers was held on Feb. 20th. The number of new patients (no transfers or renewals) was 4113, of whom 1183 were under fourteen years of age, and 1908 were from places beyond the town. The number of in-patients was 517. The average time of stay in the hospital was 16·2 days. Of the 489 major operations, 62 were extractions of cataract in old persons. These make a total of 340 consecutive extractions, without a single case of suppuration following the operation. The income for the year was £2179 16*s.* 10*d.* The expenditure was £1955 1*s.* 8*d.* The investment fund amounts to £11,250.

GREENOCK INFIRMARY.—The annual meeting of the subscribers was held on the 17th inst. The admissions during the past year to the fever house were 145 more than in 1890, and there was an addition during the same period of 66 cases admitted to the medical and surgical wards. The ordinary income exibits an increase of £1597 6*s.* 1*d.* over the previous year, arising chiefly from the larger amount received from public boards for the treatment of fever patients, and from workmen's contributions. It may be stated, however, that the amount paid by public boards includes £900 for cases treated in the previous twelve months, but not paid till last year.

MEDICAL NOTES IN PARLIAMENT.

Foot-and-Mouth Disease.

IN the House of Lords, on Monday last, the Earl of Cadogan, in answer to Lord De La Warr, said no further facts had been elicited, and from stringent inquiries which had been made it appeared that there was no reason to believe the report that the disease had been introduced by raw hides which had been imported.—Mr. Chaplin also referred to the same thing in the House of Commons.

Sanitation in relation to Gipsy Life.

The Bill promoted by Mr. George Smith for bringing gipsy and van children under educational and sanitary influences will be introduced to Parliament next week. Mr. Burt will have charge of it.

Bill to Amend the Coroners Act, 1887.

On Friday, Sir Walter Foster laid on the table of the House a Bill to Amend the Coroners Act, 1887. It dispenses with the formality of "viewing the body," unless the coroner considers it needful or the jury after having heard the evidence express a desire to do so. The coroner, if the measure became law, would be the only person required to view the body after the present fashion. Amongst the backers of the Bill are Mr. H. S. Wright, Mr. Addison, and Mr. J. R. Kelly.

Taxes on Food.

On Friday, Feb. 19th, Mr. Picton gave notice that he would move, "That taxes on tea, coffee, and dried fruits are objectionable as taxes on food, unjust in their incidence, and ought to be abolished."

The Shop Hours Bill.

In the House of Commons on Wednesday last Mr. Provand moved the second reading of the Shop Hours Bill, which proposes to re-enact certain regulations of the Act of 1886, which expires at the end of this year. These provisions prevent young persons of either sex under the age of eighteen being employed in shops, warehouses, or public-houses for more than seventy-four hours a week, including meal times. The Bill, whilst re-enacting these clauses, applies them to adult women, and provides for the appointment of an inspector to enforce the law. Mr. Gedge moved an amendment declining to interfere with the hours of female labour until women had obtained the Parliamentary franchise. This amendment was afterwards withdrawn. After many members had

Digitized by Google

taken part in the debate.—Mr. Matthews said that the Government would not intervene as a Government, but wished the House of Commons to take the matter into its own hands. As an individual member of the Government he had to say that the result of his inquiries was not favourable to the Bill. It dealt with adult women in a manner which had not been done in the Factory Acts. The only ground that he had heard for legislation was the medical ground, but he had found no evidence to support the statement that the health of adult women was injured by their labour in shops, although long and in some sense excessive. If anybody asserted that mortality among shopwomen was excessive, he should like to know on what basis such an assumption was made. He would vote against the Bill, but if the House of Commons thought it was a subject for inquiry by a Select Committee, that could be done whether the second reading was accepted or rejected. On a division being taken, 175 voted for the second reading and 152 against. The Bill was then read a second time amid loud Opposition cheers, and on the motion of Mr. Provand was referred to a Select Committee.

Food and Drugs Act.

Mr. Parker Smith has given notice of his intention to introduce a Bill to amend the Sale of Food and Drugs Act, 1875.

Gresham University.

The Charter of the proposed new Teaching University for London was laid before Parliament on Monday last.

And in the House of Commons on Thursday Mr. Chamberlain presented a petition from provincial schools of medicine in England—Birmingham, Bristol, Leeds, Liverpool, Manchester, and Sheffield—praying that the Draft Charter for the proposed New University be not sanctioned by Her Majesty. The petitioners expressed the opinion that the provisions of the Draft Charter, if sanctioned, would admit of a degree in medicine being granted to graduates who had not been examined by the Universities authorities, except in one, and that the final examination; that any such narrowing of the scope of medical education in metropolitan Universities must inevitably tend to lower the standard of attainment which had hitherto been demanded of candidates who desired any degree in medicine; that special advantages for obtaining medical degrees on easy terms would be offered to students who studied in metropolitan hospital schools which would be denied to those studying in provincial schools; and that thereby provincial schools of medicine, together with the hospitals connected with them, would be placed at serious disadvantage and their efficiency impaired.—In reply to Mr. Bartley on Thursday evening Mr. Balfour said he would do his best to endeavour to meet the views of those interested in the matter by stopping public business at 11 o'clock, but the exact date would depend on the course of public business.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ATKEY, P. J., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

BANKS, A., L.R.C.P., M.R.C.S., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

BEVAN, RICHARD, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health, Ashford, Kent.

BOGAN, J. H., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Fethard, No. 2, Dispensary District, Medical Attendant to the Constabulary, Irish Light, and the Admiralty, Duncannon Fort, co. Wexford.

BOX, C. R., B.Sc. Lond., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

BURDEN, H., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

CLAYTON, J. H., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Casualty Surgeon to the Queen's Hospital Birmingham, vice Clay, resigned.

CROSSFIELD, A. K., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer for the Dittisham Sanitary District of the Totnes Union.

DALZELL, A., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Special Department for Diseases of the Throat to St. Thomas's Hospital.

DICKINSON, J. C. H., M.B. Camb., L.S.A., has been appointed Medical Officer of the Workhouse, Stepney Union.

EASBY, W., M.D., has been reappointed Medical Officer and Public Vaccinator of the Castor District of the Peterborough Union.

FAIRBANK, F. R., M.D Heidelb., L.R.C.P. Lond., M.R.C.S., M.R.C.P. Edin., has been appointed Honorary Consulting Surgeon to the Doncaster Infirmary.

FISHER, J. H., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Special Department for Diseases of the Ear to St. Thomas's Hospital.

FORDE, T. A. M., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

HAYDON, T. H., B.A., M.B., B.C. (Cantab.), L.R.C.P., M.R.C.S., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

HUMPHRY, F. A., F.R.C.S., has been appointed Honorary Consulting Surgeon to the Sussex County Hospital.

KELLOCK, T. H., M.A., M.B., B.C. (Cantab.), F.R.C.S., L.R.C.P., has been appointed House Surgeon to St. Thomas's Hospital.

LAKEMAN, THOMAS, L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer for the Ugborough Sanitary District of the Totnes Union.

LATTER, C., B.A., M.B., B.C. Cantab., has been reappointed Resident House Physician to St. Thomas's Hospital.

LOVELL, C. P., M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.P., L.S.A., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin to St. Thomas's Hospital.

MARSH, J. H., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Third A Sanitary District of the Hailsham Union.

MCCREERY, J. O., L.R.C.S. Irel., has been appointed Medical Officer for the South Brent Sanitary District of the Totnes Union.

MILTON, W. F. E., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

MORRIS, EDGAR, M.R.C.S., has been appointed Honorary Surgeon to the Hereford General Infirmary, vice Vevers, resigned.

OBASA, PRINCE ORISADINE, L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat to St. Thomas's Hospital.

PERKINS, J. J., B.A., M.B., B.C. (Cantab.), L.R.C.P., M.R.C.S., has been appointed Non-resident House Physician to St. Thomas's Hospital.

PHILLIPS, P. C., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin to St. Thomas's Hospital.

PICKEN, JAMES, M.B., C.M. Glasg., has been reappointed Medical Officer of Health for the Urban Sanitary District of the Rawmarsh Union.

PURVIS, W. P., B.Sc. Lond., L.R.C.P., M.R.C.S., has been reappointed Non-resident House Physician to St. Thomas's Hospital.

REYNOLDS, E. S., M.D. Lond., M.R.C.P., M.R.C.S., has been appointed Medical Officer of the Crumpsall Workhouse, Township of Manchester.

ROCHE, ANTONY, M.R.C.P.I., L.R.C.S.I., L.M., has been appointed Examiner in Sanitary Science in the Royal University, Ireland.

SIMPSON, E., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Calverton Sanitary District of the Basford Union.

SMITH, K. R., M.D. Lond., B.S., M.R.C.S., has been reappointed Medical Officer for the Harberton and Halwell Sanitary Districts of the Totnes Union.

STOKES, A. W., F.C.S., has been appointed Public Analyst for Hampstead, vice Heisch.

THOMAS, E., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Aberdaron Sanitary District of the Pwllheli Union.

TURRELL, W. J., M.A., M.B., B.Ch. Oxon, has been appointed Medical Officer to the Cutler Boulter Provident Dispensary, Oxford.

URSDELL, HENRY, M.R.C.S., has been reappointed Medical Officer for the Staverton and Rattery Sanitary Districts of the Totnes Union.

VINCENT, HERBERT E., M.D., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed to the Staff of the Croydon General Hospital, vice Dr. P. T. Duncan, resigned.

WALLACE, C. T., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Special Department for Diseases of the Ear to St. Thomas's Hospital.

WATSON, F. S., M.R.C.S., has been appointed Medical Officer for the Linton Sanitary District and the Workhouse of the Linton Union.

WILLIAMSON, J. HENRY, M.R.C.S., L.R.C.P. Lond., has been appointed Junior House Surgeon to the Ancoats Hospital.

WYMAN, C., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Resident House Physician to St. Thomas's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Birmingham.—Assistant House Surgeon. Salary £50 per annum, with apartments and board.

BRIDGEWATER INFIRMARY.—House Surgeon. Salary £80 per annum, with board and residence.

BURTON MEDICAL ASSOCIATION.—Dispenser. (Apply to Mr. A. Blant, Ebenezer, Shobnell-road, Burton-on-Trent.)

CAMBERWELL HOUSE ASYLUM, Camberwell, S.E.—Junior Medical Officer. Salary to begin at £100 a year, with board, lodging, washing &c.

CANCER HOSPITAL (FREE), Fulham-road, S.W.—Two Surgeons.

CENTRAL LONDON OPHTHALMIC HOSPITAL, 238A, Gray's inn-road, W.C.—House Surgeon.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer. Salary (which will be a progressive one) commences at £100 a year, with furnished apartments, board, washing, and attendance.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon. Salary to commence at £85 per annum, with board, residence, and washing in the house. (At end of year a gratuity of £15 is usually given by the committee.)

DISTRICT INFIRMARY, Ashton-under-Lyne.—Assistant House Surgeon and Dispenser. Salary £50 per annum, with board and lodging.

EAST SUFFOLK AND IPSWICH HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

GUARDIANS OF THE POOR OF PADDINGTON.—Assistant to the Medical Superintendent of the Infirmary, and Assistant Medical Officer of the Workhouse. (Apply to the Medical Superintendent at the Infirmary, 285, Harrow-road, W.)

TEIGNMOUTH, DAWLISH, AND NEWTON INFIRMARY, DISPENSARY, AND CONVALESCENT HOME.—House Surgeon (to act as Secretary). Salary £40, with board and lodging.

THE RETREAT, York.—Junior Assistant Medical Officer. Salary £80 per annum, with board, lodging, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician for six months. Board and lodging provided.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Surgeon for six months. Board and lodging provided.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon. Salary £50 per annum, with board and residence in the hospital.

Births, Marriages, and Deaths.

BIRTHS.

CARDEW.—On Feb. 18th, at Dennington-park-road, West Hampstead, the wife of H. W. D. Cardew, M.R.C.S., of Harley-street, of a son.

FULLER.—On Feb. 20th, at Bughrooke, near Weedon, the wife of Andrew Fuller, Surgeon, of a daughter.

GARNHAM.—On Feb. 19th, at the residence of her father (Rowden-hill, Chippenham), the widow of Dr. G. J. W. Garnham, of Smalley, Derby, of a son.

HILL.—On Feb. 18th, at Middlesex County Asylum, Upper Tooting, the wife of H. Gardiner Hill, Medical Superintendent, of a son.

HILL.—On Feb. 19th, at St. Margaret's Mansions, S.W., the wife of W. J. Hill, Esq., M.B., D.P.H., of a daughter.

MACKAY.—On Feb. 19th, at Northumberland-place, North Shields, the wife of W. Murray Mackay, F.R.C.P. & S., L.P.S.G., &c., of a daughter.

STALKER.—On Feb. 18th, at 140, Nethergate, Dundee, the wife of Alexander M. Stalker, M.D., of a son.

STEVENS.—On Feb. 20th, at Springfield, Tulse-hill, S.W., the wife of A. B. Stevens, M.B. Oxon, of a daughter.

MARRIAGES.

APPLEFORD—SEARGEANT.—On Feb. 23rd, at St. Mary's, Kemsing, Kent, S. Herbert Appleford, M.D., youngest son of the late William Appleford, of Coggeshall, Essex, to Mary Annie Seargeant, daughter of the late John Seargeant, of Grange-hill, Upper Norwood.

CROUCHER—CHAPLIN.—On Feb. 18th, at St. Mary Magdalen Church, St. Leonards-on-Sea, Alexander Henry Croucher, M.D., of Eastbourne, second son of Dr. Croucher, J.P., to Mary Rebecca, elder daughter of A. Chaplin, Esq., Chapel-park-road, St. Leonards-on-Sea.

CROUDACE—ROWE.—On Feb. 20th, at St. Andrew's Church, Stoke Newington, James Henry Croudace, Surgeon, of Stafford, to Elsie Emma, second daughter of T. B. Rowe, Esq., of Glan Llyn, Stoke Newington.

REYNOLDS—SANSOM.—On Feb. 23rd, at St. Marylebone Church. Ernest J. Reynolds, L.R.C.P., M.R.C.S., to Rose Ernestine Maria, eldest daughter of A. Ernest Sansom, M.D., F.R.C.P., of Harley-street, W.

DEATHS.

GARDINER.—On Feb. 14th, at his residence, Redcliff-hill, Bristol, George Gardiner, M.R.C.S., aged 72.

PEARSE.—On Feb. 22nd, at St. George's square, S.W., suddenly, George Pearse, M.D., aged 80.

TAYLOR.—On Feb. 15th, at Scarborough, suddenly, John William Taylor, M.D., D.Sc., Medical Officer of Health, Scarborough, and of North Riding of Yorkshire, aged 54.

WILLETT.—On Feb. 21st, at Gunnersbury House, Isleworth, Edmund Sparshall Willett, M.D., J.P., aged 61.

YOUNGER.—On Feb. 19th, at 19, Mecklenburgh-square, W.C., Edward Henry Nelson, the dearly loved son of Edward and Frances Younger, aged 8 months.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births Marriages, and Deaths.

BOOKS ETC. RECEIVED.

Medical Diary for the ensuing Week.

Monday, February 29.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.
ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.
LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital: 1 P.M., Mr. Wm. Lang: Diseases of the Iris.—Great Northern Central Hospital: 8 P.M., Dr. Galloway: Cardio-vascular System.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. F. Wethered: The Diagnostic and Prognostic Value of Tubercle Bacilli in the Sputum.—Mr. Spencer Watson: The Effects of Intra-nasal Obstruction on the General Health.

Tuesday, March 1.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.
GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Professor V. Horsley: The Brain.
LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars: 4 P.M., Dr. Payne: Seborrhœa and Allied Affections.—Bethlem Hospital: 2 P.M., Dr. Percy Smith: Insanity and Organic Brain Disease.—Charing-cross Medical School: 8 P.M., Dr. Boxall: The Rational Employment of Antiseptics in Midwifery.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—5 P.M. Annual General Meeting.
PATHOLOGICAL SOCIETY OF LONDON.—Adjourned Discussion on Phagocytosis and Immunity by Dr. J. S. Bristowe, Dr. Sidney Martin, Dr. M. A. Ruffer, Mr. C. A. Ballance, Dr. W. Hunter, Mr. E. H. Hankin, Dr. E. A. Wright, Dr. J. C. Adami, Mr. Cartwright Wood, Mr. T. J. Bokenham, and others. Card Specimen by Dr. C. Slater: Cultures and Preparations of Leprosy Bacilli.

Wednesday, March 2.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.
CHARING-CROSS HOSTITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.
LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Dr. C. Theodore Williams: Asthma.—Royal London Ophthalmic Hospital: 8 P.M., Mr. A. Stanford Morton: Ocular Paralysis.—Parkes Museum (Margaret-street, W.): 1 P.M., Dr. Louis C. Parkes: Communicable Diseases.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Handfield Jones and Dr. Horrocks. Three papers on Cæsarean Section will be read by Drs. Leith Napier, John Shaw, and Cullingworth.

Thursday, March 3.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.
ROYAL INSTITUTION.—3 P.M. Professor W. P. Ker: The Progress of Romance in the Middle Ages.
LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond-st.: 4 P.M., Dr. Arkle: Pathological Demonstration—Tuberculosis.—National Hospital for the Paralysed and Epileptic: 2 P.M., Mr. B. Brudenell Carter: Ocular Symptoms in Diseases of the Nervous System.—London Throat Hospital, Gt. Portland-st.: 8 P.M., Dr. Woakes: Necrosing Ethmoiditis.
SOCIETY OF ARTS.—4.30 P.M. Surgeon-General Sir William James Moore: Indian Sanitation and the International Congress of Hygiene.
HARVEIAN SOCIETY (Stafford Rooms).—8.30 P.M. Mr. Lockwood and Mr. Cosens: Traumatic Infection (illustrated with Micro-photographs). Dr. Lewers: A case of Face Presentation illustrating the Value of Axis Traction Forceps.

Friday, March 4.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Dr. C. Theodore Williams: The Compressed Air Bath and its Uses.—Bacteriological Laboratory, King's College: 11 A.M. to 1 P.M., Professor Crookshank: Erysipelas and Suppuration (Streptococci).—Charing-cross Medical School: 8 P.M., Dr. Boxall: Obstetric Operations (a practical demonstration with mannikin and stillborn fœtus).
WEST KENT MEDICO-CHIRURGICAL SOCIETY (Greenwich-road).—8 P.M. Mr. Bruce Clarke: The Radical Cure of Prostatic Enlargement by the Galvano-cautery.—Dr. Lewis Jones will undertake the management of the Electrical Apparatus.
ROYAL INSTITUTION.—9 P.M. Professor L. C. Miall: The Surface-Film of Water and its Relation to the Life of Plants and Animals.

Saturday, March 5.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.
LONDON POST-GRADUATE COURSE.—Bethlem Hospital: 11 A.M., Dr. Percy Smith: Insanity and Syphilis.
ROYAL INSTITUTION.—3 P.M., Right Hon. Lord Rayleigh: Matter, at Rest and in Motion.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

MORE DRINKING.

WE record with shame and regret the fact that last year the United Kingdom drank more than the year before to the amount of one million and three-quarters. The consumption of spirits amounted to 30,744,209 gallons, or 1,833,778 gallons more than were consumed in 1890. This is an appalling fact, even though the rate of augmentation of beer consumed is said to be rather below the average. It is our profession that sees the results of this increased traffic in alcohol in the degradation of personal and family life. We cannot pretend to say how it is to be stopped. If the evil could be taken out of the category of questions over which parties fight and make capital, something would be achieved. It is a disgrace to all parties alike.

R. M. C.—1. It is necessary if an unassailable right is desired. The prefix is often accorded by courtesy to Bachelors of Medicine. 2. It is not incorrect. It is a matter of taste. Too much assertion of one's titles, however good they are, is in bad taste.

Victoria.—The Brussels would appear to be the only available degree under the circumstances stated by our correspondent.

Tyro.—We think not, but application had better be made to the secretary of the College.

CLUB DOCTORS AND THEIR PATIENTS AT CHUDLEIGH.

LOCAL affairs must be rather dull at Chudleigh just now. The *Western Daily Mercury* devotes an article to club doctors and their patients, a large part of which is occupied by the abuse of the local club doctors for alleged disrespect to club patients, and to high praise of the clubs for discarding all the local profession, and, through advertisement in our columns, inviting candidates, who came from all quarters—at least, from Ireland, from France, and from Eastbourne. We must say we are very sceptical as to the truth of the charges brought against the medical men of "insulting" their club patients. This is so entirely contrary to probability and experience that we shall require to have definite facts before we believe it, and we regret that any contemporary should bring such railing accusations against resident medical men in such vague terms. The article ends with a eulogy on the stranger introduced which must be as distasteful to him as the abuse of his brethren with which it is associated, and on which it is based. He has our sympathy.

Mr. A. Codd.—Some have held that water containing salts of lime in abundance may cause digestive disturbance or promote constipation, or may intensify any tendency that exists to calculous disorders; while others have contended that the mineral substances may usefully supply some of the salts required for the construction and repair of tissues, and that the existence of lime-salts in such water is not altogether disadvantageous, especially in the case of young growing subjects. We would refer our correspondent to "A Handbook of Hygiene," by G. Wilson, M.A., M.D. (London: J. and A. Churchill), for further particulars on this point. An official report, containing analyses of the London water-supplies, including that of the Kent Company, is issued monthly. Ordinary washing soda, added in proper proportion, will remove both temporary (carbonate) and permanent hardness (sulphate).

Sanitarian.—The matter was treated pretty fully in THE LANCET of the 16th ult. An instructive sequel will be found in our present issue.

L.S.A.—The possessor of the licence does not confer the privilege of using the title "Dr."

TREATMENT OF DISEASE BY ELECTRICITY.

To the Editors of THE LANCET.

SIRS,—Has not the study and use of electricity been somewhat neglected by the profession? Having seen good results from its use in some cases lately I may mention two as examples. 1. A lady unable to get her food into her stomach save by mechanical means, arising from atony of the muscles concerned in the function of deglutition. She lost health and spirits, became emaciated, after consulting medical men in the town where she was residing, and afterwards in the metropolis, taking a variety of medicines prescribed, but without the least benefit; in despair she went to an electrician, and after a course of his treatment was soon able to take her food as before, and has recovered her health and spirits. 2. A patient of the same operator, still under treatment, informed me that, from troubles and anxiety of mind connected therewith, he by degrees became so dyspeptic that at last his stomach had lost all power, and his mind became weakened as well as his body. He consulted medical men, went through all sorts of tonics, including pepsine, but without the least benefit. Under the electrical treatment his stomach has by degrees regained power; he can enjoy a light breakfast of cocoa and toast &c., and a dinner generally of fish, followed by a milk pudding. He has regained his weight, looks happy, and seems able to reason very well, only he has lost all respect for doctors, and swears by his electrical friend. Not being now in practice, I have never made use of this remedy, but a good many years ago in India when often having to treat cholera cases I used to wish that I might have been able to do so.

The present epidemic in its diffusion, variety, and intensity of symptoms, also in its weakening effects, has some resemblance to cholera, also in treatment, which seems to be nursing and treating symptoms as they occur. One of your correspondents looks upon influenza as a neurotic disease—probably it is—and the brain and eighth pair of nerves (which by-the-by are ganglionic) have to do with it.

In a recent number of THE LANCET Dr. Goodhart, in his interesting lecture on some forms of dyspepsia, one from a "dulled and flabby nervous spleen," states "there is a time to give drugs, and a time when to give drugs is quackery!" The remedy is to give advice. In such cases one might advise change of air to the seaside or some Highland place where the air is pure and dry, as at Balmoral, or to Cairo in the winter; but how many can follow such advice? It is much easier to cross the street and go to an electrician, which would be my advice in such cases as described by Dr. Goodhart, and I should expect thanks from my patient when his cure was completed.

I am, Sirs, yours faithfully,

Feb. 16th, 1892. SENEX.

F.R.C.S.E. &c.—The charges seem to be reasonable and ought to be paid willingly. The nature of the professional service, not to say of the practice, seems to have been somewhat unusual. In such cases it would be well at the outset to have an understanding as to fees.

Dentist.—Our correspondent would no doubt be acting advisably in taking the step indicated.

COMPARATIVE MEDICAL LITERATURE.

THE *North Carolina Medical Journal* institutes a comparison between THE LANCET and some American journals. It refers to the library of the Surgeon-General's office as a veritable cemetery of medical periodicals. At or about the time of its *début* thirteen American medical journals were in existence, all of which were worthy representatives of medical science, but with no other foundation than the reputation of the editors as teachers and leaders in thought. In the case of THE LANCET, its present life may be due to the impress and influence of its founder transmitted through successors in the same family—circumstances that are very exceptional. It has, says our contemporary, maintained a distinct standing in its presentation of the literature of medical science that has made it the most popular of the medical journals in the world. The writer asks, "How could the English-speaking doctors of the world supply the loss of such a welcome weekly visitor to their offices?" The article goes on to state that "for the first week of the year 1892 the issue contained 120 double-column pages of reading matter and 80 pages of advertisements, which would be, in the type usually employed in medical text-books octavo size, the equivalent of from 400 to 500 pages." *The North Carolina Medical Journal* advises its readers, if this information should be new to them, "to try a year of teaching from THE LANCET and see if they will not find great profit."

Mr. Ernest W. Greenwood.—Our correspondent seems to be unaware that the name "Albert" has been changed to "Gresham."

INJUSTICE UNDER THE NOTIFICATION ACT.

To the Editors of THE LANCET.

SIRS,—Referring to the letter of "J. W." in this day's LANCET, I should be obliged if you would state whether an urban sanitary authority, or its medical officer, has power to question the accuracy of a certificate given under this Act. A case has come under my notice where Dr. —— gives a certificate that a patient is suffering from a certain fever; a few days after Dr. ——, who takes up the case, certifies that the person is suffering from a lung trouble, and not from any infectious disease. This coming to the knowledge of the authority, they decline to allow the notification fee. Can they refuse it, even though the diagnosis be wrong? Do you know if a legal decision has been given in a similar case? I am under the impression that it has, but cannot come across it. I am, Sirs, yours truly,

Feb. 20th, 1892. B. M.

*** We are not aware that any legal decision of the sort has been come to, and we trust that it will be long before it is asked for. It is quite clear that cases must arise where diagnosis is doubtful, and on which medical men might differ. A medical man whose diagnosis in a case of notification is challenged would do well not to press his claim *unless he is very confident of being right*. But our correspondent puts his question as if the notifier in this particular case were wrong. Possibly in strict law, even so, if he acted *bonâ fide* he might be able to compel the payment of his fee by the sanitary authority. But we should not envy him his success. Let such an incident be viewed from the patient's standpoint. The wrongful notification of his disease as infectious within the meaning of the Act might involve his contracting a deadly disease. He is entitled, in case of any doubt, to a second opinion. If it refutes the first one, it clearly should not be persisted in: it should be withdrawn, and with it the demand for a fee.—ED. L.

W. R.—It is not easy, on the information before us, to give an opinion on all the points raised. Thus, in many such districts as the one in question, the culverts with which house-drains were originally connected were not "sewers" properly so-called, but highway drains, and the new culverts are in reality the first sewers provided. As regards the term "new building," its application to existing buildings which undergo modification is limited by Section 159 of the Public Health Act, 1875, where it is enacted that for the purposes of that Act "the re-erecting of any building pulled down to or below the ground floor, or of any frame building of which only the framework is left down to the ground floor, or the conversion into a dwelling-house of any building not originally constructed for human habitation, or the conversion into more than one dwelling-house of a building originally constructed as one dwelling-house only, shall be considered the erection of a new building." Nothing whatever is said to imply that the laying of a new drain constitutes a "new building."

CARPENTER AND DUKES DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Kindly insert these additional subscriptions to the above fund, and oblige, Yours faithfully,

An Entire Page	5 5 0

The Publisher cannot hold himself responsible for the return of testimonials &c. sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 65, Rue Caumartin, Paris.

Lecture
ON
NEUROLOGICAL FRAGMENTS.

Delivered before the Hunterian Society,

BY J. HUGHLINGS JACKSON, M.D., F.R.S., &c.

MR. PRESIDENT AND GENTLEMEN,—I am exceedingly obliged by the request to undertake the honourable task of giving the Hunterian Society's Lecture this year. It is for me a most pleasant thing to deliver it at the request of my greatly valued friend Dr. Stephen Mackenzie, our late President.

I have often thought that the scientific investigation of insanities may be best begun in general hospitals, and especially by taking for study cases of delirium in such non-nervous maladies as pneumonia and emphysema with bronchitis. These are not cases of insanity at all in the conventional sense of that word; but in a scientific regard, being departures from normal mental states, they are. After the late Dr. Monro, I have urged that the mental condition in all insanities short of dementia is double—one of two opposite mental elements. In the hospital cases adverted to the insanity is named after the positive element—delirium; but with this there coexists a negative element, if for convenience I may speak of a negative state existing. On this basis we may sometimes trace an increasing double departure from normal mentation. In cases of emphysema with bronchitis we can observe a gradual losing touch with present surroundings (negative element), and a gradually increasing quasi-relation to organised experiences of former surroundings (positive element); or using popular, but not accurate, language, the patient gradually ceases to live in the real world, and comes to live more and more in a world of his own. A sack dealer was delirious during erysipelas. The house-surgeon opened a small abscess in one eyelid while the patient was in a strait jacket. The patient's account of these circumstances was that he had been to a public-house, that the landlord fastened him down with two sacks, and then poked out one eye.

It is easy in this case to trace the substitution of unrealities, as we call them, for realities. I wish to urge that we have not only to take into account the patient's "pseudo-knowings"—that he had been to a public-house &c., his delirium sampling a positive element,—but also his "not-knowings"—that he was in hospital &c., sampling a coexisting negative mental element. We say that the patient's account was of a delusion ("pseudo-knowings"); there was a delusion for us, but in him a belief. To say that he believed in his delusion is the tautology of saying that he believed in his belief. The late Dr. Milner Fothergill gave an account of his delirium when ill with scarlet fever. It seemed to him most unreasonable that people should keep him in bed when he, a doctor, wished to go out to visit his patients. For Fothergill, when reduced to a lower mental state, it was, to use his words, "an interference with the liberty of the subject." By these remarks I wish to suggest that what we call the "disorderly" mental condition of an insane man—that sampled by his positive mental symptoms—is a mentation having the same laws as the mentation of the patient's former sane, or, as we may say, entire, self.

Let us now look at the physical condition concomitant with insanities—the two abnormal cerebral states corresponding to the two abnormal mental elements. The negative mental state—the sack-dealer's "not-knowings"—signified loss of function of the highest range of his highest cerebral centres. (If anyone objects to the term "highest centres," he can substitute "certain cerebral centres.") The mentation remaining possible to him—his "pseudo-knowings"—signified increased activities of the intact lower ranges of those highest centres. We have here loss of function coexisting with over-function, and an illustration of a principle long ago put forward by Anstie and Thompson-Dickson. We have to bear in mind both the reduction (dissolution) and the range reduced to (the level of evolution remaining). The positive element of an insane man's mental condition signifies evolution going on in lower intact ranges of his highest centres.

In hospital we can study degrees of insanity. Thus in some severe cases of emphysema and bronchitis there is delirium followed by coma, the coma or dementia being a greater degree not of the delirium, but of the negative mental state coexisting with that positive or superpositive state. Referring to a former remark, the patient, who gradually ceases to live in the real world, and comes to live in a world of his own, at length, when comatose, lives in no world at all (mentally, I mean). I attribute the "two degrees" of insanity in cases of emphysema partly to great supervenosity, to different degrees of it. The neurologist is much interested in the effects of supervenous blood. Here I make some general remarks on the action of such blood. It is well known that it stimulates certain medulla centres, whether by excess of carbonic acid or by deficiency of oxygen does not for the present concern us. Most likely a slight degree of supervenosity is beneficial in cases of emphysema by stimulating the respiratory centre, thus producing some degree of compensation. Traube and Cohnheim attributed the hypertrophy of the left side of the heart in some cases of emphysema to arterial constriction caused by stimulation of the medulla vaso-constrictor centre by supervenous blood. Such blood stimulates certain musculatures; here, perhaps, we see the reason why there are evacuations in some cases of nitrous oxide anæsthesia.

Now for delirium with, and, as I think, partly if not mainly from, highly supervenous blood, in cases of emphysema and bronchitis, for example. Since it is certain that such blood over-stimulates some lower (for example, medulla) centres, the obvious explanation of the delirium in cases of emphysema with bronchitis would be that it corresponds to over-stimulation of cerebral centres. But (Hitzig, Franck, Pitres) asphyxia renders the motor cortex inexcitable. Dr. Risien Russell has recently made for me a new research in this matter. He finds that the motor cortex of a dog is inexcitable in the third stage of asphyxia. It does not necessarily follow that because asphyxia annuls the function of the motor area that it renders the remainder of the cortex functionless. I, however, submit as a hypothesis that supervenous blood, according to its degree of venosity, diminishes or annuls the function of all parts of the cortex. If this be so, it cannot be the cause of delirium, which evidently implies function going on. In a popular use of the word "cause," as when it is said that opening floodgates causes water to flow, supervenosity may be called the cause of delirium. But speaking carefully, we can only say that it is constructively accountable for that positive mental element; it produces the negative functional state answering to the negative mental element coexisting with the delirium. I explain the relation of the two states on the same general principle as I did the condition in the sack-dealer's case. The highest, the least organised, range of the highest centres is rendered functionless when the lower and more strongly organised ranges of those centres remain functionable; the lower ranges being now uncontrollable rise in activity, and during their activity delirium occurs (Anstie's principle). (The more complex and special nervous arrangements are the less organised, and thus they "give out" sooner to injurious influences.) When the supervenosity becomes very great the lower ranges of the highest centres also succumb, and then no sort of mentation, not even the "disorderly" mentation we call delirium, is possible I have been speaking as if supervenosity were the sole agent; but since from highly supervenous blood there will be very great stimulation, and perhaps at length exhaustion of lower (medulla) centres, the condition is probably more complex.

The study of degrees of insanity in relation to one another is very important. This can best be done by noting degrees of reduction (dissolution) of brain by alcohol. I, it may be supposed artificially, make three degrees of reduction (with subdegrees) In considering these degrees of insanity we have to take note of the coexisting negative and positive states—of the reduction of the highest centres (dissolution) and of the range reduced to (evolution remaining)—until the third degree coma, acute temporary dementia, when the mental condition is seemingly entirely negative, and the reduction of the highest centres apparently total.[1]

[1] The neurologist will find in Brain, January, 1881, a most valuable paper, by Dr. Charles Mercier, on Degrees of Dissolution by Alcohol.

Digitized by Google

For purposes of practice we have to study alcoholic intoxication carefully. It is well known that men fatally ill from cerebral lesions are sometimes locked up in police cells for drunkenness. It needs insisting on that there may be from grave intra-cranial lesions, soon causing death, not only insensibility, but manner and conduct like that of a person partly intoxicated by alcohol. Dr. Stephen Mackenzie and I have recorded[2] a fatal case of meningeal hæmorrhage producing a condition which, without the history of onset, would—certainly by the non-medical—have been taken for drunkenness. The patient was violent, swore, and, what is more striking, there was a purposive action; the patient got the chamber utensil from under his bed and used it. At the London Hospital we occasionally have under care men who, after sucking raw spirits out of a cask, are seemingly as deeply comatose as other men are after large and fatal cerebral hæmorrhage. Without the history of the circumstances and of the mode of onset, the diagnosis of apoplexy produced by alcohol from that produced by cerebral hæmorrhage is very difficult, and may be impossible. For an hour or two after injuries to the head there may be a condition very like that of a man slightly drunk. This is an important matter. I was once consulted by letter on the case of a clergyman who was accused of drunkenness—a serious thing for a clergyman. I was able to say that the condition described might have resulted from an injury to the head the patient had had. It is to be borne in mind that after an injury to the head a patient may act elaborately, if foolishly, whilst "unconscious"; that is, on his recovery he *remembers* nothing of his strange doings—a thing evidently of medico-legal importance.

I have suggested[3] that great supervenosity may cause loss of the knee-jerks, as when there is great cyanosis in severe cases of emphysema with bronchitis, and that possibly the absence of this tendon reaction in some cases of apoplexy is thus caused. Dr. Risien Russell was so good as to observe for me the state of the knee-jerks in an artificially asphyxiated dog; he found that they were increased during the earlier stages of asphyxia, and lost in the third stage. I suggested[4] that the preliminary increase of the knee-jerks Dr. Russell observed was owing to lack of inhibition of lumbar centres by the motor cortex, and that the loss of the jerks in the third stage was owing to the more strongly organised lumbar centres succumbing later than the cortical motor centres. Dr. Russell[5] brought forward interesting facts showing that my inference was at any rate hasty. Dr. Stephen Mackenzie, who has had a large experience of cases of anæmia, including many cases of "pernicious anæmia," tells me that he has never found loss of the knee-jerks in any case. I mention this as supervenous blood may tell by deficiency in oxygen. Rapidly induced loss of oxygen is, however, a very different thing from slow loss of oxygen (loss of many oxygen carriers in anæmia).

There is another complication. I have recorded[6] a case of epileptiform seizure affecting mainly the left leg, in which, after the fit, the left knee-jerk was exaggerated; there was also foot clonus. Westphal, Gowers, and Beevor have noted temporary loss of the knee-jerks after epileptic fits. I suggested that the exaggerated knee-jerk in my patient was owing to exhaustion of fibres of the lateral column, whereby cerebral control was taken off the anterior horns concerned with the jerk.[7] Dr. Gowers suggests that in the case of temporary loss of the knee-jerks after epileptic fits there is temporary exhaustion of the lumbar nuclei. As in the animal Dr. Russell experimented on there had been convulsion, we have to bear in mind that the loss of the knee-jerks may have been due, or partly due, to exhaustion of lumbar centres after their discharge. Dr. Beevor remarked on this point at the meeting above mentioned. His researches on the condition of reflexes after epileptic fits[8] have to be carefully considered with regard to the question here raised.

I had the honour of reading a paper before this Society on Laryngismus Stridulus,[9] when I submitted that the paroxysms are asphyxia fits analogous to those producible artificially in rabbits and dogs. I tried to show that the relation of rickets to these seizures (Elsässer, Jenner, Gee) is that the abnormally soft ribs render the action of the diaphragm inefficient (the infant's breathing being almost solely abdominal), and thus that, especially during sleep, when the attack commonly starts, there is over-stimulation of the respiratory centre by supervenous blood, an excess of a "natural stimulant," and therefrom convulsions. Dr. Gay[10] has very ably argued against the views I put forward. I do not here reply to his criticisms, but will mention some things bearing on my speculations. When I wrote (1886), Horsley and Semon had discovered "representation" of the abductors, but not of the adductors, of the vocal cords in the medulla, and thus it *seemed* that there was no medulla mechanism by which (on my supposition of discharge beginning in the respiratory centre) the glottis could be closed in attacks of laryngismus. Semon and Horsley have since found that the adductors as well as the abductors of the vocal cords are represented in the medulla. Asphyxia fits are easily producible in some lower vertebrates of the mammalian class by mechanical arrest of breathing. These seizures, the physiologist tells us, are owing to discharge beginning in the (medulla) respiratory centre, a discharge started by highly supervenous blood; the discharge there beginning no doubt spreads to other centres, or possibly they are discharged by the same stimulation. 1. Convulsions are produced by clamping the trachea. 2. Curara in a certain dose paralyses the motor nerve endings to the respiratory muscles, and not those of the muscles of the limbs; asphyxia is produced, and there is convulsion of the limbs. The discharge of the respiratory centre in these circumstances is unable to effect anything upon the thoracic musculature. 3. Rabbits breathe almost exclusively by the diaphragm. Marckwald says that young rabbits "up to four months old, and even over that age, do not survive division of the phrenic nerves on both sides, but die, according to age, in a few minutes after the operation, showing strong convulsions and cyanosis, or in two or three days they die from asphyxia."[11] Probably the respiratory centres are stimulated by supervenous blood because it is deficient in oxygen.[12] 4. For (Kussmaul and Tenner) fits like those produced by clamping the trachea are produced in rabbits by rapidly bleeding them to death. 5. Such fits come on when the medulla is deprived of arterial blood by tying the great arteries of the head. 6. Artificial respiration will not prevent asphyxial convulsions by a drug if that drug stops the action of the heart, and thus arrests the circulation.[13] "Stoppage of the heart, either by a ligature directly applied to it, or by action of drugs upon it, causes asphyxia and convulsions."[14]

Of course, it does not follow from anything I have just said that laryngismus stridulus in man (the infant human being) is an asphyxia fit, as I think it is. But it would be worth while to study in minute detail the onset and march of convulsions in laryngismus stridulus, especially when they become widespread or universal, in comparison and contrast with the onset and march of convulsions in artificially asphyxiated animals. The difficulties of this comparative study are obvious, but sometimes a medical man witnesses a fit of laryngismus. Since, according to my hypothesis, in laryngismus stridulus the blood, when it has become rapidly supervenous, discharges the respiratory centre, and thus secondarily causes still more supervenosity by fixation of the thoracic cage or some part of it, it may seem that the fit on that hypothesis would necessarily be fatal. Thus Dr. Gay says[15] of my

[11] The Movements of Respiration, translation by Mr. Thomas A. Haig.
[12] Although, as is the custom, one uses the word "stimulation," the supposition is that, from lack of oxygen, there is such an anabolism of material of the respiratory centres that it becomes more "explosive," and thus katabolises on slight provocation, suddenly and excessively. There are convulsions in some cases of nitrous oxide anæsthesia. Thus Dr. Frederic Hewitt writes (Med.-Chir. Trans., vol. lxxiv.): "The clonic contractions of the respiratory and extrinsic laryngeal muscles occur at or about the same time that clonic muscular phenomena in the extremities manifest themselves, and there can be little doubt that they are, like the latter, *due to an absence of free oxygen*. I have lately administered at the Dental Hospital of London, for Dr. George Johnson, *pure nitrogen*, as well as nitrogen with small percentages of oxygen, and the respiratory phenomena which have manifested themselves, as well as the general muscular movements, have so closely resembled those of nitrous oxide as to be indistinguishable from them." hypothesis; "Supervenosis initiates the paroxysm, which increases the supervenosity, and laryngismus would consist of a single and necessarily fatal gigantic respiratory spasm." My friend Dr. Risien Russell has been so good as to make experiments for me bearing on this matter; he clamped the trachea of three rabbits. He reports: "If the clamp was removed in the third stage from thirty to fifty seconds after all convulsions (second stage) had ceased the animal recovered without artificial respiration being performed, but if the clamp was not removed until a minute or more elapsed the animal did not recover. The heart went on beating after all the respiratory movements had ceased. An artificially asphyxiated dog recovered without artificial respiration two minutes after all convulsions (second stage) had ceased." A child, when seemingly dead after an attack of laryngismus may recover. Sir William Jenner[16] reports a very striking illustration of this. Not only is the opinion I hold of the pathology of laryngismus disputed, but the suggested localisation of the discharge on which the attack depends is also objected to. It is supposed by Horsley and Semon that fits of laryngismus are owing, not as I think to discharge beginning in a medulla (respiratory) centre, but to discharge beginning in a part of the cortex-laryngeal centre. They have certainly good reasons for this supposition. Krause, Horsley, and Semon have discovered representation of the adductors of the vocal cords in the cortex, but have not discovered representation of the abductors in the cortex, except in the case of the cat. (The cat, Semon tells me, vocalises during inspiration.) Discharge of the laryngeal centre of but one cerebral hemisphere will close the glottis (Semon and Horsley). This closure would, if kept up, cause asphyxia: but, as I learn from one of their experiments, the blood when it has, on this enforced closure of the glottis, become supervenous, so acts on the medulla as to bring the (medulla) abductor centre into activity. Horsley and Semon write:[17] "Unilateral irritation [of the laryngeal area of the cortex] produces bilateral effect. Thus, clinically, in any irritative unilateral affections of this area, spasm of the glottis, that is, bilateral adduction of the vocal cords, may occur, for example, in laryngismus stridulus. That this view is not theoretical is shown by the association, in severe cases of the last-named illness, of the glottis spasm with the so-called carpo-pedal contractions. This association is most easily explained on the assumption that we have any overflow of energy from the laryngeal to the neighbouring cortical areas for the limbs."

In some laryngeal crises (laryngismus of a different clinical kind from that already considered) there is asphyxia; there may be loss of consciousness and some degree of convulsion. I have now under my care a tabid patient who has had twenty or thirty crises in the day with loss of consciousness, and four severer seizures in bed (one after urgent vomiting and three in sleep) also with loss of consciousness. The four attacks in bed, judging from the accounts given by the patient's wife, are not unlike epileptic fits. This patient has paralysis of the abductors of the vocal cords (Semon), no doubt from a lesion of their medulla centres. This ordinarily does not seem to embarrass the patient's breathing, he being quiescent. Semon tells me that he thinks that in laryngeal crises, with or without paralysis of the abductors, there is an "irritative" state of the (medulla) adductor centres. If so, it is to occasional overaction of these centres, greatly narrowing or completely closing the glottis, that laryngeal crises are owing. I have never witnessed such severe laryngeal crises as, by description, my patient has had. If I was present at one of his seizures I should, if I could not abort the paroxysm by chloroform, very carefully note the state of his thorax, observe minutely any convulsions (eyes, hands, and face) there might be, note whether or not there was increased sweating, and inquire if there were evacuations of urine or fæces, and, if it were possible, test his knees.

Neurologists are much concerned with Regulation, and, in many maladies, with Unregulation. There is (1) nervous regulation, which needs no illustration here; (2) mechanical regulation (elasticity of arteries, &c.); and (3) what for lack of a fit name I will call "chemical regulation," stimulation of the respiratory centre by venous blood, for one example. Properly speaking there are three factors in regulation. In the case of the respiratory system (1) the (medulla) respiratory centre with its afferent and efferent nerves; (2) elasticity of the lungs and of the thoracic walls (recoil during expiration); (3) stimulation of the respiratory centre by venous blood. I shall speak almost solely of the third factor, the other two being taken for granted. What is waste in one manufactory may be material for another. What is waste for one part of the body may be material for another (Treviranus and Paget). Thus I suppose that one factor in keeping up arterial tonus in health is stimulation of the vaso-constrictor centre by effete nitrogenous products—a "natural stimulant" of that centre. An excess of a natural stimulant is a poison. High tension in some cases of Bright's disease is probably owing to an excess of the natural stimuli mentioned, and perhaps also to the presence of unnatural stimuli of similar derivation. I have suggested that attacks of laryngismus are owing to a sudden excess of a "natural stimulant" of the respiratory centre. In some cases of simple jaundice the pulse becomes infrequent. This is ascribed to stimulation of cardio-inhibitory nervous elements by bile salts. It would be venturesome to speak of this as due to the action of an excess of a *natural stimulant*, since there is, I believe, no proof that bile salts exist in the blood of the healthy. There is one thing worth mentioning in this connexion. Henoch says that he has never observed an infrequent pulse in the jaundice (catarrhal) of children under seven years of age. He supposes that the excitability of the child's nervous system compensates for the retarding action of the bile acids. But may it not be that there is less for the bile salts to poison in persons so young? The cardio-inhibitory, and probably other inhibitory nervous arrangements (Soltmann), are presumably developed later than what may be distinguished as the directive (motor) nervous arrangements. (Perhaps this is only another way of saying that the child's nervous system is excitable.) As bearing on the hypothesis I have submitted, it may be mentioned that both rabbits and young children tolerate large doses of belladonna; it is well known that in the rabbit section of the vagus nerves alters the rate of its heart but little.

We have a very complex problem in regulation—or, rather, in unregulation—in cases of fracture dislocation of the spine, crushing the cervical cord across below the emergence of the phrenic nerves. The nervous mechanisms of the digestive, circulatory, respiratory, and animal heat systems—the "four systems"—are mutilated; there is constipation with "distension" of the abdomen; the pulse is infrequent; respiration is diaphragmatic only; temperature is often very high. For the methodical analysis of this compound confusion of regulation we have to take into account not only centres of the Lowest Level, which are Ulterior (peripheral wards) of the lesion, but also those of this level which are Citerior (brainwards) of the lesion. It is, I think, not going too far to say that the whole symptomatology is, in late stages, traversed by supervenosity. There is in the spinal fracture case as certainly an anatomico-physiological problem as there is in the case of subphrenic section of the cervical cord in a dog or a rabbit. Surgeons and physicians would gain much from the coöperation of a well-trained physiologist in the investigation of the effects of such a very local spinal cord lesion in man compared and contrasted with those in the dog, and especially with those in the very different vertebrate, the rabbit, similarly mutilated. In some cases in man there is delirium: an example of a healthy brain failing consequent on a very local spinal cord lesion—consequent on that lesion in a roundabout way—directly owing to the results of imperfect working of the "four systems" mentioned. Hence, in the spinal fracture case, in which the central nervous system is cut in two at a critical place, we have to take note of all centres of the nervous system. Further, as it is said that supervenous blood excites certain musculatures apart from nervous agency, we have to take also into account many, perhaps all, parts of the body.

Taking, quite artificially, but one symptom, great rise of temperature in some cases of fracture dislocation (subphrenic cervical cord), we find it very difficult of interpretation. The greater rate of emission of heat may not signify greater thermogenesis. Very many of the muscles—the main heat-producing organs—are "paralysed"; and thus it may be supposed that there is less thermogenesis. We cannot make calorimetrical researches on our patients. Paralysis is an indefinite word. In the case of a dog poisoned by curara, all the skeletal muscles are cut off from the motor influence of the whole central nervous system; an animal thus poisoned becomes "cold blooded." But in the fracture dislocation case

[16] THE LANCET, Jan. 2nd, 1875.
[17] Brit. Med. Jour., Dec. 21st, 1889.

Digitized by Google

muscles are "paralysed" in a very different way; they remain connected with their anterior horns, and it is fair to speculate that they may not only continue to produce heat, but that, being cut off from higher inhibitory heat centres, they may produce more than normal. I have been speaking of "paralysis below the lesion"; there is no doubt, from destruction of grey matter of the part of the cord crushed, some "paralysis at the lesion"; but the amount of muscle thus cut off from the influence of the central nervous system is a negligible quantity. If the "muscles below the lesion" cease to produce heat, then, as Hutchinson has said, they become refrigerators—have to share in the heat produced by "muscles above the lesion." A patient of the late Mr. Hilton lived fourteen years after a fracture dislocation crushing the cervical cord across below the emergence of the phrenic nerves. Did not the "muscles below the lesion" in this man produce heat when they were "paralysed"? If they did not, they would have had to share the heat produced by the "muscles above the lesion" (and of course by other parts of the body), and would thus be refrigerators.

A question in neurology—one of great physiological interest and clinical importance—is raised by certain researches of Charlton Bastian.[18] He showed that in some cases of an absolutely complete transverse lesion of the cord above the lumbar enlargement the knee-jerks were absent and the legs flaccid up to the time of death three or four months later. This is quite contrary to current doctrine. So far as I have observed in cases of fracture dislocation crushing the cervical cord completely across, the knee-jerks are lost—to take that one symptom for illustration. I am greatly interested in this matter, since Bastian's conclusions harmonise with a hypothesis I have put forward as to cerebral and cerebellar influxes. It may be said that did the patients referred to live long enough their knee jerks would return. In some dorsal cases under my care the knee jerks have returned—in one case after being absent for thirty-eight days, and in another for two years; there is in neither case any return of sensation or motion in the legs. But granting for the sake of argument, and for the sake of argument only, that there has been no re-establishment of lines of connexion in these cases, we have still to explain the absence of the jerks for weeks and months, in conditions where shock was out of the question. If Bastian has only shown that the knee-jerks are absent for weeks or months he has made a valuable contribution to clinical medicine; I should still think that the doctrine of cerebellar influx is countenanced. The situation is not so simple as it has been supposed to be. In many such cases (Bowlby) the superficial reflexes are present, or, if absent at first, may return. It has been said that when in chronic cases the knee-jerks are absent there are set up secondary morbid changes in centres below the lesion, and perhaps in peripheral nerves; we have, however, to explain not only the loss of the tendon reaction, but also the presence of the superficial reflexes. There is priapism in cases of fracture dislocation of the cervical spine; it may be (Hutchinson) present in "shock." Does not this show over-action of some elements of Stilling's nucleus? Moreover, those who suppose that secondary morbid changes set up in centres below the lesion cause loss of the knee jerks for months have to account for the return of these tendon reactions in some cases. Are those morbid changes reversed or in part reversed? We have, with regard to the doctrine of cerebellar influx, to bear in mind that in many cases of tumour of the middle lobe of the cerebellum the knee-jerks are absent. I may mention a case (necropsy) of hæmorrhage into the left lobe of the cerebellum (observed by Dr. Penberthy, my late house physician) in which the right knee-jerk only was lost; I say nothing as to the bearing of this case.

I have applied the doctrine of non-antagonised cerebellar influx in the explanation of athetosis and paralysis agitans, supposing that in both, upon loss of cerebral influence, there is preponderance of cerebellar influence. It is right that I should state facts counter to this application of the hypothesis. Victor Horsley, by removing the "arm area" of one of his patients, put a stop to athetosis. There is on record[19] a case of cerebral hæmorrhage occurring in a patient the subject of paralysis agitans; the tremor ceased on the side of the body paralysed, continuing on the other.

[18] Med Chir. Trans., 1890, vol. lxxiii.
[19] Raymond: Hemichorea.

The symptoms of disorder (unregulation) of the organic systems—very strikingly of the respiratory—are most important. When death occurs in apoplexy from cerebral hæmorrhage it is with failure of the respiratory system, and presumably of the other organic systems. These failures may be put down to lack of so much brain, but not rarely *do* we see patients who live for years with much more extensive destruction of brain than that by a hæmorrhage which may kill in a few hours. They may be ascribed to the wider abnormal state of the brain which answers to loss of consciousness, or perhaps to pressure indirectly transmitted to the medulla oblongata. I have to suggest a different interpretation.

In some cases of cerebral hæmorrhage, where there has *not* been loss of consciousness at first, and in which respiration, circulation, and temperature have been apparently normal for some time, disorder of these systems ensues later on. There is, what many years ago I used, after Trousseau, to call "cerebral fever." In such cases it seems to me that the "fever" depends, not on the immediate effects of the effusion, but on secondary effects the clot produces in medulla centres. To consider methodically the question here raised we should study cases of other "foreign bodies"—tumours, abscesses, and other masses in the brain. In these cases it is notorious that there is one distant effect. Optic neuritis is nearly always set up, and I submit that, adopting the principle of a hypothesis put forward by Buzzard,[20] there are other "distant effects," that morbid changes akin to those of optic neuritis are set up in medulla centres. We certainly have, in very many cases of optic neuritis from cerebral tumour, to explain the urgent "purposeless" vomiting. Moreover, in such cases there may be a chronic illness with occasional vomiting, infrequent pulse, constipation, and emaciation. In a few cases of cerebral tumour there is an acute illness very like tubercular meningitis. Further, it is notorious that some patients who have cerebral tumour die suddenly. *It* is not at all likely that death occurs from the destruction the tumour causes directly, or by the softening induced round about; it is not likely that it occurs from mere lack of so much cerebral hemisphere. Again, as the late Hilton Fagge first pointed out, death occurs rapidly in some cases of intracranial tumour by respiratory failure. It may be asked, "Why does respiration in such cases fail rapidly?" I can only suggest an analogy. It is well known that sight may be good in optic neuritis for a long time, and then rapidly fail. So I imagine that in the cases mentioned morbid changes are slowly produced in the respiratory medulla centre, and that that centre fails rapidly, perhaps having worked inefficiently some little time before. After irruption of blood in the brain that blood becomes a clot, acts as a "foreign body," produces a local encephalitis, and by intermediation of this there are set up secondary morbid changes, changes in centres (respiratory among them) of the medulla. This is of course hypothetical. At any rate, in a case of large cerebral hæmorrhage, it is at least convenient to distinguish several modes of action of the escaped blood: (1) It destroys, and thus produces such symptoms as hemiplegia; (2) according to the rate of its escape it causes "shock"; (3) according to its bulk it squeezes, and thus, in addition (2), it produces loss of consciousness; (4) in its character as a "foreign body" it may produce encephalitis, and thereby, hypothetically, "cerebral fever" by changes induced in medulla (regulating) centres. But this is not all; (5) in some cases of cerebral hæmorrhage, in which consciousness, if defective, has not been lost at the onset, delirium may occur. I submit that this is mainly a "return effect" on the brain, a consequence of imperfect working of the respiratory and other organic systems, a state of things analogous to that in the dilirium of some cases of emphysema with bronchitis, and in some cases of cervical fracture dislocation of the spine.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.—The report for the year 1891 shows that 15 per cent. more patients had been dealt with than in any previous year, the largest number during any twelve months since the infirmary was opened. The income showed a small deficit, the disbursements necessarily being more, owing to the additional number of patients relieved.

Lecture
ON
TISSUE- OR CELL-FIBRINOGEN IN ITS RELATION TO THE PATHOLOGY OF BLOOD.

Delivered at the Theatre of the Laboratories of the Conjoint Colleges of Surgeons and Physicians, on Feb. 4th, 1892,

BY A. E. WRIGHT, M.D. DUB.,
LATE GROCERS' RESEARCH SCHOLAR.

(Concluded from page 459.)

KEEPING therefore in view those phenomena which are observed after an injection of tissue-fibrinogen, we have to bring them in connexion with the phenomena observed after injections of leucocytes. These phenomona have been studied by Groth, Wooldridge, and Krüger. I have already indicated in connexion with Wooldridge's work that the method of experimentation he adopted appears to exclude from the injection all the rapidly disintegrated a-leucocytes, and such products of their disintegration as would naturally pass into solution in the lymph plasma. On the other hand, in the methods of Groth and Krüger there is either no provision (in the case of Groth's experiments) or ineffectual provision (Krüger's experiments) is made for the elimination from the injection of such elements of the lymph plasma as have not been derived from leucocytes. Having said thus much in criticism of the methods, we may pass on to the results obtained by these observers from their injections. Krüger and Groth both succeeded in obtaining intra-vascular coagulation with their injections. They, further, noticed that when the injections of leucocytes were not sufficiently large to entail such intra-vascular coagulation, the blood, when collected after the lapse of a few minutes, showed a very marked diminution of coagulability. The results Wooldridge obtained were in all cases a diminished coagulability of the blood after injections of washed leucocytes. It will be immediately evident that in the case of Groth's and Krüger's experiments we have to deal with the same sequence of positive and negative variation which we are now familiar with in connexion with tissue-fibrinogen injections. In Wooldridge's experiments we have only a negative phase of coagulation put on record. In connexion with this I would make the suggestion that a very transient positive variation may very easily have occurred here and have escaped notice. Groth has emphasised the fact that such a positive variation is sometimes so transient that it is necessary to draw off a sample of blood during the actual progress of the injection in order to satisfy oneself of the actual occurrence of such an increase of coagulability, and we have seen confirmation of this in the case of the protocol which has been quoted (*supra*, p. 459). It is therefore probable that Wooldridge's failure to obtain evidence of the occurrence of a positive variation of coagulability after his leucocyte injections was attributable to his not withdrawing a sample of blood immediately after his injection was completed. I believe, therefore, that Wooldridge's experiments do not in the least contradict those of Groth and Krüger. And it may be accepted that the phenomena of a positive phase, succeeded by a negative phase, are to be observed in exactly the same way after a leucocyte injection as after a tissue-fibrinogen injection. The identity of an injection of leucocytes with an injection of tissue-fibrinogen is also brought out by the results of Groth's leucocyte enumerations of the white corpuscles in the blood. These enumerations yielded the result that not only are the leucocytes of the circulating blood not increased by the large injections of leucocytes, but they are, on the contrary, positively diminished even in cases where no intra-vascular coagulation can be detected. This will become evident on the consideration of the following figures which I have extracted from Groth's paper:—

	Before injection.	After injection.
	Number of white corpuscles in the blood.	
Experiment 5	10,483	6115
" 6	29,265	5678
" 7	17,908	2512

It is thus evident that the increase of coagulability after leucocyte injection is associated with a breaking down not only of the injected but also of some at least of the aboriginal leucocytes of the blood, and this breaking down of leucocytes must evidently go hand in hand with a setting free of tissue-fibrinogen in the blood.

Up to the present we have been dealing exclusively with injections of leucocytes derived from the lymphatic glands, and we have to amplify the data thus obtained by a study of the effects of leucocytes derived from other sources. Here, again, we are indebted to Schmidt's pupil, Dr. Groth. Groth determined that the addition of pus cells to the circulating blood was followed by very similar results to those which resulted from the intra-vascular injection of lymphocytes. The phenomena of the positive phase—i.e., those of intra-vascular coagulation—were, however, much less prominent, and the negative phase was, on the other hand, perhaps rrelatively more marked than with lymphocytes. These observations have an important bearing upon the causation of the negative phase, inasmuch as the prominence of the phenomena of the negative phase after pus injections probably stands in close relation to the very considerable quantity of "peptone" or albumoses which Hoffmeister's researches have shown to be present in pus either as actually pre-formed or in such loose combination that the addition of moderate quantities of alkalies is sufficient to set them free.

I have now laid before you merely the broad facts which seem to me to point to the identity of the phenomena which are observed when, on the one hand, leucocytes, or, on the other hand, tissue-fibrinogen is injected into the blood, and if that connexion has been sufficiently established, it will necessarily follow that wherever we get a disintegration of leucocytes in the blood we have to deal with a setting free of tissue-fibrinogen. This liberation of tissue-fibrinogen in the blood will result in an immediate increase of the coagulability of the blood, which, if it does not culminate in immediate intra-vascular coagulation, will last only until such time as the organism shall have been able to accomplish the breaking down of the tissue-fibrinogen into albumoses. Further, we have to remember that when this reactive process is accomplished we are introduced to a negative phase of decreased coagulability which in its turn gradually passes off by the excretion of the albumoses in the urine. According to this view, therefore, the disintegation of leucocytes, the liberation of tissue-fibrinogen in the blood and the excretion of albumoses constitute a closely inter-related sequence of symptoms which must be constantly manifesting itself in the course of all such pathological processes as go hand in hand with an increase of leucocytes in the blood. I believe that the clinical facts do in effect bear out this view. The pathology of croupous pneumonia, for instance, supplies us with, I think, a very well marked instance of the inter-relation between the three members of our symptom-sequence. We have first an enormous increase of the numbers of the leucocytes, which, though they are for the most part to be found outside the vessels, are yet in immediate relation to them. We have then, especially when the stage of absorption is reached, the well-marked increase of coagulability in the blood, which I take it is due to the absorption of tissue-fibrinogen.[1] We have, further, the well-known occurrence of peptonuria, or rather, as Lea Dickinson and Fyffe have shown, of albumosuria; and in connexion with the presence of albumose in the blood we have, as Dr. Dickinson has pointed out, the frequent occurrence of diarrhœa, which, I may remark in passing, is also very frequently seen in connexion with injections of tissue-fibrinogen. The other cases of what we may call peptonuria—for the distinction between peptone and albumose is, after all, a very much over-rated one—are associated with pyæmic conditions and with the defervescence period of certain fevers, such as measles or scarlatina. Here, again, we are probably dealing with leucocyte disintegrations. Further, we have the peptonuria of osteo malacia, which, however, is apparently not an invariable accompaniment of that condition, but rather an accompaniment of any

[1] Since the date of this lecture I believe that I have definitely established this by preparing large quantities of tissue-fibrinogen from consolidated pneumonic lungs, which were very kindly obtained for me by my friends, Dr. H. S. Rolleston and Dr. E. H. Starling. A few cubic centimetres of the solution of this tissue-fibrinogen, when injected intra-vascularly, gave the typical universal thrombosis in a rabbit and the typical portal thrombosis in a dog.

Digitized by Google

proliferation of the cells of the bone marrow, whether arising from that cause or from the presence of tumours. Lastly, we have the peptonuria of phosphorus poisoning, which is also probably due to the increase of leucocytes in the blood which is described in connexion with that condition. All these cases of what we may for convenience call peptonuria may be grouped together under the term of "hæmatogenous peptonurias."[1] I believe they are probably all due to a disintegration of tissue-fibrinogen in the blood. In contradistinction to these we have the class of what have been called "pyogenous peptonurias," because they occur wherever we have a mass of disintegrating pus in the body, provided the conditions are favourable to the absorption of the products of such decomposition. It is evident from the researches of Hoffmeister, which I have referred to above, that the further disintegration of the leucocyte, or of the tissue-fibrinogen which is liberated from it, into albumose may occur in the abscess itself, instead of in the blood. In that case we would, of course, not have any positive phase of coagulability from the absorption of tissue-fibrinogen.

We have thus seen that peptonuria is probably in all cases associated with an increase in the number of leucocytes in the system, and that an increase of coagulability in the blood is only to be expected where the primary product of their disintegration—i.e., the tissue-fibrinogen—obtains access to the blood. Generally speaking, this will occur when the leucocytes disintegrate in the blood stream itself. Further, the greater or less coagulability of the blood will generally depend upon the number of leucocytes present. We have an apparent exception to this last rule in the case of leucocythæmia, where, as is well known, the coagulability of the blood is decreased rather than increased. The explanation of this exception, however, here lies readily to hand, for the increased coagulability we have spoken of all along is a relation which obtains only as between leucocytes and normal plasma, and in leucocythæmia, as Jacob v. Samson-Himmelstjerna (another of Schmidt's pupils) has shown, the power which the leucocythæmic plasma has of breaking down the cellular elements of the blood for the purpose of fibrin formation is diminished, while the power possessed by the cellular elements of contributing a fibrin factor to the coagulation of healthy plasma is still retained.

The clinical evidence is thus apparently conclusive that the sequence of symptoms, increased production of leucocytes, increased disintegration of leucocytes in the blood, increased coagulability, subsequent peptonuria, is one which does not infrequently manifest itself; but as the importance of the subject seems to render it desirable to obtain even further experimental evidence upon this subject, I have endeavoured to make some further observations in connexion with this complex of symptoms. Two methods of experimentation suggested themselves. It was evidently possible, if a method of increasing the leucocytes in the circulating blood could be discovered, (*a*) to employ that means of increased production with a view to attaining a subsequent increased disintegration of the leucocytes in the blood by the natural destructive processes of the body, and, further, (*b*) it was possible to bring about the artificial disintegration of such leucocytes as exist at a particular moment in the circulating blood by the administration of some drug such as quinine (Binz) or atropine (Horbaczewski), which possesses this property of disintegrating the leucocytes present in the blood. I have as yet made a few preliminary experiments in each of these directions. My experiments in the first direction have been of a more or less incidental character, and were obtained in the course of experiments upon the question of immunity from anthrax, as obtained by means of injections of Wooldridge's tissue-fibrinogen. I noticed in connexion with these that some of my rabbits which were being put through a course of preparation for anthrax inoculation, consisting of daily injections of tissue-fibrinogen solution, died before the period for that inoculation arrived; and the post-mortem examinations revealed the existence of discoloured branching coagula in the heart and great vessels, which must evidently have been formed during the lifetime of the animals. Here we had, therefore, a late coagulation as a consequence of tissue-fibrinogen injection, a phenomenon for which I was totally unprepared. Some time afterwards, in reading over Groth's work on the injection of leucocytes, his figures, which pointed to an enormous increase of leucocytes in the blood two or three days after the injection of leucocytes, arrested my attention. I have verified these observations in some twenty rabbits in the case of injections of sterilised tissue-fibrinogen solutions, and have seen the leucocytes invariably considerably increased—sometimes increased to as many as six times their normal number. The subject is one which I am following up in connexion with its evident bearing on the causation of immunity by tissue-fibrinogen injections. What interests us, however, here is only the fact that an increase of leucocytes in the blood stands in evident relation to an increase of coagulability. With regard to the second method of experimentation—viz., the administration of quinine for the purpose of artificial disintegration of the leucocytes in the blood—I am not prepared yet to make a positive statement; but in several experiments which I made upon the subject I obtained at first an enormous increase of coagulability; and though I have in no case succeeded in discovering any intra-vascular coagulations under these circumstances, still it is at any rate suggestive that it has frequently been suggested that the blindness which sometimes comes on after the administration of poisonous doses of quinine may be due to retinal thrombosis, and I find that De Schweinitz[2] of Philadelphia has recorded at least one case in which quinine blindness in a dog was associated with thrombosis of the ophthalmic and retinal veins. That thrombosis is not of frequent occurrence after quinine is probably due to the fact that the system would be thoroughly well able to cope with an amount of fibrinogen comparable to that which would be derived from the disintegration of a normal quantity of the leucocytes present in the blood.

With this I have completed the survey of facts which I had prepared to lay before you on the afternoon originally fixed for this lecture. Since that time I have, however, come across a communication which has just been published by the very eminent Austrian observer, Horbaczewski, and which completes for us a whole missing chapter of our subject. I am only too conscious that I have already almost exceeded the limits of time appointed to me, so I will only ask to be allowed to put his results before you in a tabular form in their connexion with the work that has been done upon tissue-fibrinogen. Before throwing this tabular synopsis upon the screen I would like to point out where the missing chapter which Horbaczewski has supplied comes into our subject. Tissue-fibrinogen, as I have previously been able to point out, is chemically a nucleo-albumen—that is to say, it is a substance which is at first sight deceptively like an ordinary protein or albuminous substance. When, however, we subject it to a peptic digestion we find that instead of passing entirely into solution it deposits a voluminous precipitate of a phosphorus-containing substance known as nuclein. Hence we conclude that tissue-fibrinogen is twi-natured, that it is by its one-half an albuminous or protein substance, and that it is by its other half a nuclein, and that these two moieties are separable from each other by the process of digestion. These properties determine its classification as a nucleo-albumen. Now we have discussed the physiological importance of the whole substance, its relation to coagulation, and the increase of leucocytes which follows its administration, and we have followed the fortunes of the protein moiety into which it disintegrates. We know that that protein moiety is excreted as an albumose. We have, however, not inquired as to what became of the nuclein moiety in the system. That is the chapter which Horbaczewski has worked out for us. Horbaczewski, I may remark, prepared his nuclein by digestion from the leucocytes of the spleen without any previous isolation of the tissue-fibrinogen.

I would now, without any further preliminaries, draw your attention to the following table.

WOOLDRIDGE'S TISSUE- OR CELL-FIBRINOGEN.

Source of tissue-fibrinogen.—The protoplasm of leucocytes, also the protoplasm of the cells of the testicle, and probably also of yeast cells.

Chemical composition of tissue-fibrinogen.—This substance is chemically a nucleo-albumen or nucleo-protein, and

[1] This term has been employed by v. Jaksch for peptonurias which are, upon his assumption, produced by the liberation in the blood of peptone "carried" by the leucocytes.

[2] Ophthalmological Review, 1891. Reported in THE LANCET, Dec. 5th, 1891.

Digitized by Google

contains a protein (or albuminous) and a non-protein (or nuclein) moiety.

Leucocyte.

Tissue-fibrinogen.	Paraglobulin and other cell proteins.

Protein moiety (is split off as albumose).	Non-protein (nuclein) moiety (xanthin bases and uric acid (Horbaczewski) obtained from this nuclein by simple chemical changes).

PHYSIOLOGICAL EFFECTS OF THE ADDITION OF TISSUE-FIBRINOGEN TO THE BLOOD.

1. *Immediate increase of coagulability* (Wooldridge's "positive phase of coagulability"). (*a*) Observed by Groth and Krüger after injections of leucocytes (intra-vascular coagulations produced). (*b*) Observed by Wooldridge after injection of solutions of tissue-fibrinogen (intra-vascular coagulations in portal area in the dog). (*c*) Observed by the author after injection of tissue-fibrinogen (intra-vascular coagulation in any vascular district where blood has been rendered adequately venous). (*d*) Probably comes under observation clinically in the increase of coagulability in the venous system in the resorption stage of pneumonia.

2. *Subsequent diminished coagulability* (Wooldridge's "negative phase of coagulability")—(*a*) Observed by Groth and Krüger after the injection of leucocytes; (*b*) observed by Wooldridge after tissue-fibrinogen injections, especially in the blood of the extra-portal vascular areas; (*c*) shown by author probably to depend upon the setting free of albumose or peptone by the disintegration of the tissue-fibrinogen in the blood; (*d*) no clinical record of occurrence.

3. *Excretion of albumoses or peptone in the urine* (referable to the protein constituent).—(*a*) Observed by the author after injection of tissue-fibrinogen solutions both in the dog and in the rabbit. (*b*) Observed clinically in connexion with the disintegration of leucocytes in pneumonia, pus-absorption, pyæmia, and proliferating tumours of bone marrow, &c.

4. *Increased excretion of uric acid* (referable to the nuclein constituent)—(*a*) Observed by Horbaczewski (in man and animals) after administration of nuclein prepared from the leucocytes of the spleen. (*b*) Shown by Horbaczewski to go hand in hand with every increase of leucocytes in the blood. (*c*) Comes under observation clinically in connexion with the increase of leucocytes in pneumonia (croupous) and leucocythæmia, burns, and scalds.

5. *Later occurring increased leucocytosis* (referable to the nuclein constituent)—(*a*) Observed by Groth two or three days after the injection of leucocytes; (*b*) observed by author after injections of tissue-fibrinogen; (*c*) observed by Horbaczewski after the administration of nuclein prepared from the leucocytes of the spleen; (*d*) possible connexion with immunity from anthrax obtained by tissue-fibrinogen; experiments with nuclein in progress.

I have not time here to go into the important issues which Horbaczewski's work opens up. I would merely point out that to the triad of symptoms which has been referred to in the body of this lecture we are now able to add two additional symptoms—namely, those that are enumerated on the table under headings 4 and 5. I would also point out that we find all the symptoms, 1, 2, 3, and 4, making their appearance in every ordinary case of croupous pneumonia, so that we may regard this disease as affording an almost classical instance of the effects of tissue-fibrinogen on the blood. The association of an increased uric acid excretion with peptonuria and with a more coagulable condition of the blood is not, however, limited to croupous pneumonia. It occurs also in connexion with, for instance, certain "rheumatic" or "gouty" conditions, and in connexion with burns and scalds. In the case of these last, we find thromboses in the portal area (leading to gastric and duodenal ulcers) associated with peptonuria and an increased uric acid excretion.

And now, in conclusion, I would desire to be allowed to express my very sincere thanks to the Councils of the Royal Colleges of Surgeons and Physicians, and more especially to the Laboratories Committee of the Conjoint Colleges, not only for their kindness in permitting me to work in their laboratories, but also for the very liberal manner in which I have been supplied with every appliance which was necessary for my work. Lastly, I feel that I have a debt of very special gratitude to discharge to Dr. Sims Woodhead for much unselfishly afforded assistance, and, above all, for his continual gift of sympathetic interest in the work upon which I have been engaged. I believe that I am only expressing what is felt equally by every other worker in these laboratories when I say for myself that the help and sympathetic interest of such a director of studies as Dr. Woodhead have come to me as an especial and superadded stimulus to endeavour that the researches which emanate from these Laboratories may be such as to justify the labour and care and expense which have been involved in their establishment and maintenance.

THE

THERAPEUTICS OF CERTAIN AILMENTS.

BY M. CHARTERIS, M.D.,

PROFESSOR OF THERAPEUTICS AND MATERIA MEDICA, UNIVERSITY OF GLASGOW.

CHLOROSIS.

THE leading symptoms of this affection, so often seen in young females at the age of puberty and from that period up to the eighteenth year, betoken an enfeebled circulation, which is dependent upon a marked deficiency of hæmoglobin, and to rectify this all authorities recommend the use of iron in large doses. But, as a rule, text-books do not descend to details as to the mode of administration. This is the important point, and to illustrate this I now give my experience of eighty cases, which during the last five years have come under my observation. I explain to the patient the object of the treatment by saying that her blood is thin, and that iron will alone do good, and that she must take it in a systematic manner. Her assent is gained by stating that if she acts as directed in less than a week there will be visible improvement of her health. This prognosis proves effectual, and she is told to take of pil. ferri or Blaud's pill three daily, and to go on increasing by one each day until fifteen at least are taken daily, and then to diminish the number by one daily. The time of taking them does not matter much, but it is better to swallow them at 9 A.M., 2 P.M., and 7 P.M. The tasteless character of the pills is mentioned, their non-aperient character explained, and in no case except one have I heard about any difficulty in swallowing them. Health is always restored in four weeks. The menses, if deficient or irregular, come on at the normal periods; but the patient should be told that the poverty of blood may return in the course of four or six months, and that it will be necessary, if this be so, to resume the treatment, beginning with the gradual increase mentioned, and going up to nine daily, and decrease by one daily. This number proves sufficient in the majority of cases, and, as a rule, there is no further relapse.

SEA-SICKNESS.

Some persons, unfortunately few in number, stand the sea well, and to them a voyage is from beginning to end a source of unmixed pleasure. Others stand it so badly that the prospect of a voyage is entertained with feelings of actual dread, or as a thing that must be endured. They expect to be sick, and this expectation is generally fulfilled. If we take a professional view of *mal de mer* we may say, more especially in relation to the treatment to be adopted, that there are two stages: first, pallor, nausea, vomiting, which is succeeded by a second stage, of exhaustion, retching, depression, and in many cases sleeplessness, or sleep not refreshing in its nature and attended by dreams of a painful character. The approach and duration of the first stage varies, but when begun it continues until the stomach is empty, and is succeeded by the second stage, which may be prolonged for a more or less indefinite period, in many cases extending even over the whole voyage. Various remedies have been advocated to avert the first stage—such as cocaine, antipyrin, nitrite of amyl, morphine, bismuth,—but at the present time it is generally conceded that no drug, or combination of drugs, cuts short an attack begun, or prevents its occurrence in those who are predisposed to it. Indeed, many believe that vomiting should be encouraged, by drinking warm water, so that the stomach may be sooner freed from its contents. In the second stage the remedies most relied upon are preparations of opium or morphine, hydrate of chloral, and bromide of potassium. Opium or

Digitized by Google

morphine, if retained, will cause sleep, but at the expense of awakening with severe headache and a lack of appetite. Hydrate of chloral is dangerous if it be given in a hypnotic dose of thirty grains, for in such a dose it markedly weakens the action of the heart and leads to great depression. Bromide of potassium is safe, and its utility is recognised. Dr. Lauder Brunton says that "in sea-sickness it is perhaps more useful than any other remedy." The great objection, however, to its use is its saline pungent taste, which renders it very objectionable when the stomach is irritated and weak, and leads to its almost immediate rejection. Besides, unless it be given in large doses, it exercises little influence on the system as a hypnotic. Yet undoubtedly the bromide contains properties which cannot be minimised, and the question is how can these properties be rendered more valuable? The answer will now be given: By bringing to its aid another drug—chloralamide—which within the last three years has become a favourite remedy in treating cases of insomnia, because it is a safe and reliable hypnotic. It is prepared by combining chloral with foramide, and is a colourless crystalline body, soluble in nine parts of water and one and a half parts of alcohol. It differs from hydrate of chloral in its less solubility and its non-toxic action. Chloral depresses the action of the heart; chloralamide does not, for in a dose of thirty grains it will cause sleep without any change in the circulatory or respiratory system. In a word, it possesses all the advantages and none of the disadvantages of chloral. It is prepared by E. Schering of Berlin, which firm has a world-wide reputation as the makers of pure and reliable chemical compounds. The combination, therefore, of these drugs—chloralamide and bromide of potassium—was much to be desired. It is, however, no easy matter to do this, at least in a palatable and presentable form, and requires the services of a skilled pharmacist. At my suggestion and after many trials, Messrs. Burgoyne, Burbidges, and Co., London, have succeeded in making a solution palatable and stable. It will suit the most fastidious taste, and the therapeutic influence of the two chief constituents is markedly aided by the addition of other adjuvants. Their preparation is known as "chlorobrom," an ounce of which contains thirty grains of chloralamide and thirty grains of bromide of potassium. In this dose, when given in cases of insomnia dependent upon nervous excitement or mental strain, sleep ensues in the course of half an hour, and lasts from six to eight hours. This sleep is most refreshing, and the awakening from it is attended by no headache, no thirst, and no depression. The patient rises as if from natural sleep, perfectly fitted to undertake the duties of daily life, and, so far as I have seen, the habit of taking it is not engendered. There is no desire for its further use except when the same condition of sleeplessness occurs. The physiological action of chlorobrom being thus potent and beneficial when administered to persons on land, it occurred to me that I would try it in cases of sea-sickness when opportunity offered. This I did in my autumn holiday, first to Norway, and then to the United States. I knew it would do good if it was retained by the stomach, and the question of giving it was narrowed down to this crucial point. It was with great satisfaction that I noted, in ten cases where I gave it after the first stage of active vomiting had ceased, that in each it was not rejected. To make assurance doubly sure, I gave samples of the solution to ship surgeons for trial, and requested them to give me their unbiased opinion as to its action. Their verdict is altogether confirmatory, as the reports which follow show. Given at the time mentioned, for this is the *sine quâ non* of its administration, it has been invariably successful. It has always been retained, and it has always done good. A lady to whom I gave it writes a graphic and telling description of her sensations when sick, and the manifest improvement which followed upon its use. "I was very restless and sleepless, indeed was unconscious of having slept any for two nights. After taking a tablespoonful I quickly fell asleep, slept the whole night, and awoke as refreshed as when sleep is natural. I took it a second time with the same result. My good health and appetite for the remainder of the voyage I attributed to those two nights' sound sleep. I had no return of *mal de mer*, nor even any of its sensations. During the homeward voyage I longed very much for a dose; had I got it after the first sickness had passed off I am quite sure I would have got all right. After sea-sickness one feels so worn out and restless; now the hypnotic, besides producing sleep, soothed one so much that these feelings quite passed away. I certainly would not care to go another voyage without having it with me." I carefully watched its action in the case of a gentleman who, in a voyage from America in the autumn, shared a state cabin with me. On the morning of the first day after leaving port he became very sick, and continued so all day. In the evening he was very restless, and the retching was extreme. I gave him an ounce of the solution. He fell sound asleep in fifteen minutes, his breathing being easy and his pulse-rate normal. He awoke refreshed after eight hours' sleep, and continued well during the remainder of the voyage. Four ship surgeons, who have tried it, report as follows. Full reports of each case treated by these surgeons are in my possession, but their publication here would occupy too much space. Dr. Nevin, s.s. *Furnessia*, Atlantic Ocean, Sept. 13th, 1891, after giving it in three cases, says: "Its effect is instantaneous." Dr. Belcher, s.s. *Circassia*, after giving it in four cases, writes: "I have grave doubts if this solution would in any way check *mal de mer* in its first stage, but I feel confident it would assist and relieve, if not cut short, subsequent suffering if wisely used, more especially in those who have either debility or other troubles to battle with." Dr. Arthur Scott, Tilbury Docks, London, Dec. 18th, 1891, surgeon to s.s. *Clan Mackintosh*, on his return voyage from Calcutta, after giving it in ten cases, writes: "It appears to me to possess the inestimable advantage of being retained by the stomach, of ensuring sleep, and of leaving the patient free from headache." Dr. Andrew Wylie, s.s. *Hispania*, Port Said, Dec. 31st, 1891, after giving it in two cases reports: "Before the solution was taken everything was vomited, but the solution was not vomited, and small quantities of food taken afterwards were retained. It secured a sleep of eight hours, and the patients on awakening had good appetites, and declared they had never felt better in their lives." From my own observations, and from the conclusions of ship surgeons which have been given, I feel justified in saying that chlorobrom has the crowning advantage of being absolutely safe. It succeeds when other remedies fail; it secures by sleep the gastric and mental repose which nature craves for; it takes away all distress, all depression, and all the indescribable but terrible sensations of *mal de mer* in its second stage.

Dose.—In the case of females the dose is one tablespoonful; in males, one tablespoonful and a half. This solution has as yet only been tested in the second stage of sickness which is observed in a sea voyage lasting longer than twenty hours, but from its action I feel inclined to suggest its adoption as a prophylactic in short voyages—as across the Channel from Harwich to Rotterdam, or from Holyhead to Ireland. If so, these two rules should be followed out: 1. The passenger should prepare for the voyage by taking for two successive nights an antibilious pill which contains mercury and podophyllin. This stimulates the biliary secretion and its evacuation by the alimentary canal. 2. When on board, and if the passage be made by the night service, the passenger should avoid taking any food, but retire to the cabin, undress, lie down, and take an ounce dose of the solution. In all probability there would be a sleep so sound as to prevent any nausea or sickness, and on awakening land would be in sight.

INFLUENZA.

In my experience of this epidemic I have most faith in prescribing salicylate of sodium (pure) in twenty-grain doses every four hours for twenty-four hours. Copious perspiration follows, and the distressing features of the affection disappear, if there be no complications; but if these be present the salicylate should be abandoned, and therapeutic measures adopted according to the extent and gravity of the case. In ordinary cases, after discontinuing the salicylate, I prescribe for a week four grains of quinine in half a glass of sherry at 11 A.M., and the same quantity of quinine in a whole glass of sherry at 4 P.M. The patient should not go out of his bedroom until the expiration of at least ten days. In cases where the nervous depression is marked even after recovery, it is advisable to order the patient to go for a change to a bracing health resort or to take a short sea voyage.

PHTHISIS.

Repeated testimony has been borne by almost every observer to the undoubted efficacy of cod-liver oil and the hypophosphite of lime in the early stage of phthisis. The

Digitized by Google

former gives nourishment to the body, and the latter exercises an alterative influence upon the process of tubercular change. Yet cod-liver oil should not be given by routine, but with definite rules as to its administration. To secure proper assimilation it should be prescribed in a teaspoonful dose at bedtime for three successive nights, then a dessert-spoonful at the same time. On the sixth and seventh days it should be taken in a dessert-spoonful dose after dinner and at bedtime, and afterwards in a table-spoonful dose after each meal. If so prescribed it does not cause eructation or nausea, and the doses may be increased in accordance with the wishes of the patient until the end of the fifth week, when it should be stopped for a week, and resumed. With each dose of the oil five grains of hypophosphite of lime dissolved in a little hot water should be taken. Thus administered, these medicines notably increase the strength of the patient, and returning health is evidenced by increased weight. If circumstances permit, and if the patient be young, a sea voyage is of inestimable advantage in maintaining the progress made to recovery, and if the voyage be to New Zealand and back in many cases the patient's health is established. I firmly believe that the hypophosphite of lime is the only form of hypophosphite of any value in tubercular disease. This opinion was expressed by me in communications to THE LANCET in 1876, when this salt was first introduced to the profession as an efficient therapeutic agent. All my subsequent experience confirms this view, and I do not consider its influence is increased by its combination with the sodium and iron salts.

CHRONIC CONSTIPATION.

Most purgative medicines, if used for any length of time, require their doses to be increased, and the habit of employing them is engendered. Cascara sagrada, on the other hand, can be prescribed with advantage in diminishing doses, and in time can be omitted altogether. Thus, a teaspoonful of the liquid extract, if given at bedtime, will cause action of the bowels after breakfast, which is accompanied by no griping and no intestinal uneasiness. The next night the dose should be fifty minims, the next forty, the next thirty, the next twenty, and afterwards a ten-minim dose should be taken for eight successive nights. As a rule it may then be discontinued, as the action of the bowels comes on in a natural manner at the same hour of the day.

ANGINA PECTORIS.

In this affection there is little doubt of the benefit of the inhalation of the nitrite of amyl or of the taking of nitro-glycerine—the latter being preferable for continued treatment. As illustrating this I shall give a short account of a case which came under my observation three years ago. I was called to see a man aged forty-five, whose condition was very pitiable. He was lying propped-up in bed, and complained of difficulty of breathing and intense cardiac pain. I prescribed a hydragogue cathartic, consisting of three grains of calomel and a quarter of a grain of podophyllin, and told him after the medicine had acted to take a tablet of nitro-glycerine twice daily. In the course of two days I saw him again, and found him much better. He has continued under my observation more or less since I saw him first, and can attend to his daily duties as a time-keeper in a large public work. The difficulty he experienced in walking with any ease has diminished by adopting a certain procedure in taking the tablets. His own words are: "There is a remarkable improvement in my health with regard to walking, and all through the tablets. By putting one in my mouth previously to starting to my work in the morning, I am able to walk at my ease to the gate-house without halting. Previously to doing this I had to halt, until the pain ceased, from three to five times, and such has been the case for over two years; I can now walk the distance in less than five minutes, and I have known it to take me twenty. I can now walk from my house to the tram-car without a halt, when it usually took me from five to seven stops."

Glasgow.

MUNIFICENT GIFT.—Mr. E. A. Pearn of Compton Leigh, near Plymouth, has given a mansion and twenty-four acres of land for the benefit of the Royal Albert Hospital, Devonport, and the South Devon and East Cornwall Hospital, Plymouth. On the land he purposes to erect a convalescent home, and will endow it for the joint use of the two institutions named. The gift has been gratefully accepted.

DISEASE OF THE TEMPORAL BONE.[1]

BY A. J. PEPPER, F.R.C.S. ENG.,
SURGEON TO ST. MARY'S HOSPITAL.

IF I were asked to mention the surgical diseases in which preventable deaths are most common I should cite strangulated hernia, perforation of the vermiform appendix, and suppuration in the mastoid cells. No doubt the majority of cases of inflammation of the middle ear and the surrounding bone tend to spontaneous cure, or at least to such amelioration as to place the sufferers apparently out of danger. I say apparently, because so long as a perforation of the tympanic membrane remains with discharge, however slight, whether continuous or intermittent, there is an abiding cause of a possible fatal issue. How often do we meet with instances of ear disease in which, perhaps, years have intervened between the initial attack and the subsequent accession of acute symptome—a renewal of the storm with its attendant threatenings. But there is another reason for the delay or neglect, as the case may be, in resorting to early operative interference. I refer to the regional anatomy of the parts affected. The close juxtaposition of the brain, the lateral sinus, and the carotid artery to the area of primary mischief has undoubtedly led the practitioner too often to defer or abandon the only treatment likely to be of the least avail. I cannot too strongly insist that such a reason implied or expressed is wholly untenable, that, in short, patients ought not to be left to a chance recovery when they can almost to a certainty be placed in security so far as life is concerned. The beneficial results offered by operation are not confined to cases where the disease is limited to the middle ear and mastoid cells, for on several occasions consecutive abscess in the brain has been successfully treated.

As regards the causes of inflammation of the petro-mastoid bone, it may be said that with few exceptions the affection is secondary to disease of the middle ear. Primary tubercular caries is comparatively rare, whilst syphilitic caries is much more so. Otitis media is usually the result of (1) some exanthematous fever, notably, scarlatina and measles; (2) disease of the naso-pharynx, such as ulceration and adenoid gowths (here the morbid change is due either to the inflammation spreading in the continuity of the mucous membrane of the Eustachian tube, or to obstruction to the escape of secretion from the tympanum); (3) exposure to cold. I will not weary the reader with detailing the sequence of events, which ends in the petro-mastoid bone being involved, but at once proceed to discuss the latter condition, its features, phases, consequences, and appropriate treatment. According to Gruber the various parts of the temporal bone are attacked in the following order of frequency:—1. The mastoid cells. 2. The roof of the tympanic cavity. Here the principal danger to be feared is extension of the disease to the middle fossa of the skull, with meningitis and abscess of the temporo-sphenoidal lobe of the brain as natural consequences. 3. The posterior wall of the meatus. In this case an abscess may form between the bone and the external ear simulating true mastoid abscess. 4. The plate of bone separating the mastoid cells from the lateral sinus, in which thrombosis of the sinus and cerebellar abscess are events to be feared. 5. The floor of the tympanum and posterior wall of the carotid canal. Congulation in the vein and hæmorrhage from the artery are possible sequelæ. 6. The petrous portion proper involving destruction of the labyrinth.

The above division is rather of pathological interest than clinical significance, for the disease is but seldom limited to the area first involved. I think it may be fairly said that few patients the subjects of chronic mastoid suppuration would lose their lives if the treatment were carried out on rational surgical lines, for even in the worst cases—providing of course that intra-cranial mischief and pyæmia have not commenced—a wide opening and free excavation of the bone by relieving tension and affording a ready escape for discharge are rapidly and surely followed by marked relief from symptoms which disquiet the surgeon and distress the patient. As regards acute cases, where dangerous and too often fatal symptoms supervene closely on abscess formation in the middle ear, there is less time in which to act, for

[1] A paper read at the Harveian Society, Feb. 18th, 1892.

Digitized by Google

blood poisoning and cerebral mischief are apt to ensue early and develop with great rapidity. Sir W. Dalby says that in this division must generally be placed the unavoidable deaths. Whilst agreeing in the main with his opinion, my own experience leads me to believe that here, too, the mortality is far higher than it should be. Let us take, for example, a case of suppurative inflammation of the middle ear accompanying, or following closely in the wake of, scarlet fever. The tympanic membrane bursts and affords an exit for the pent-up pus. There is a temporary lull in the symptoms, the pain lessens, and the temperature falls. But soon the danger signals are full set again. What can the surgeon do more than use antiseptic injections, apply leeches, and carry out minor details which together make up the orthodox routine of treatment? If the mastoid cells are invaded, as they usually are, there is a resource left which ought at once to be employed—viz., to remove the outer plate of bone and break up the septal walls of the cells. I have practised this on several occasions, and always with complete success. There is no time to wait for fluctuation, œdema, or redness to manifest themselves externally, and there is no occasion for it. Deep-seated aching in the bone is always present; and, moreover, gentle percussion, and even pressure with the finger, suffices to increase the pain even when the superficial soft structures appear, and are in reality unaffected. I cannot lay too great stress on this fact. In cases like the above one has to meet the liability to suppuration in the skull, thrombosis of the lateral sinus, and pyæmia. The disintegration of septic clot in the sinus is a common cause of embolism and metastatic abscess. Thrombosis of the lateral sinus is indicated amongst other signs by œdema and swelling of the side of the neck. Besides, the coagulation is apt to extend along the internal jugular vein, which can sometimes be felt as a solid cord. In such a state of affairs treatment offers little chance of success, but still it should not be abandoned in despair. Given a certain diagnosis of a septic thrombus in the sinus, I would not hesitate to lay it open. The liability to hæmorrhage, immediate and secondary, must be kept in mind. Even should such a disaster happen, it would not be difficult to arrest the bleeding. I have seen the patent sinus entered by a trephine and the patient recover. Touching intra-cranial suppuration, I may here note that abscess in the brain from middle-ear disease is found either in the cerebellum or the temporo-sphenoidal lobe of the cerebrum. It is more common in the former situation, except in very early life, when the reverse obtains. The reasons why cerebral abscess is the rule in young children may be supplied, perhaps, by the following facts:—1. The petro mastoid and squamosal bones only undergo ossific union during the first year of life. Prior to this, suppuration may extend with readiness from the middle ear to the cranial cavity, the pus making its way through the thin intervening plate of cartilage. 2. The mastoid process is not formed until the second year, and the mastoid cells are not developed before the age of puberty. Although the mastoid bone contains in the first years of life a soft, jelly-like tissue which forms a favourable nidus for suppuration, the pus is not locked up, as it were, under pressure in bony cells. The least resistance is through the petro-squamosal suture and along the passage which transmits the large petrosal nerve. Relatively, too, I believe in very early life the plate of bone bounding the posterior fossa of the skull is thicker than that forming the roof of the tympanum.

I now proceed to discuss the principal complications of chronic disease of the petro-mastoid bone, and, first, I will treat of *facial paralysis*. From the long course the facial nerves take through the temporal bone extending from the internal auditory meatus to the stylo-mastoid foramen, and from the fact that there is sometimes a natural breach in the wall of the Fallopian aqueduct on its tympanic aspect, it is somewhat curious that it so often escapes being implicated. Facial paralysis from ear disease is relatively a rare event. It must always be considered a significant one, since we see how readily the inflammatory process may extend along the nerve to the cranial cavity. Symmetrical paralysis from double ear disease I have not seen. Now and then the nerve on the side opposite the bone lesion is affected. This may result from basic meningitis, but far more frequently it is part of a hemiplegia from abscess of the brain. Whether arising directly from the bone disease, or at a later stage from meningitis, the paralysis is as a rule general in its distribution, and not seldom total in quantity. On the other hand, when it participates in one-sided palsy of the body, the muscles of the upper part of the face may be expected to retain their power, wholly or partially. The following case, whilst illustrating this point, may be looked upon as an epitome of neglected ear disease, consequent on naso-pharyngeal adenoid growths.

W. F——, aged nine, was admitted under my care into St. Mary's Hospital on April 14th, 1890. This is his history. From July, 1888, to 1889 he breathed with his mouth open. There was no deafness and no paralysis, and his sight was good. In October, 1889, he began to lose his sight, and shortly after a discharge was noticed from his *left* ear. In December, 1889, a lump formed behind his left ear, which burst in January, 1890. About this time paralysis of the lower part of the *right* facial nerve and of the right arm manifested itself. Three months later the right leg was noticed to be weaker than the left. There had been no convulsions. In March, 1890, he was under the care of Dr. Bond, at the Golden-square Hospital. At that time there was offensive discharge from the left ear, and a sinus over the mastoid bone. He was almost absolutely blind. The pupils were large and equal; they acted but little to light. The ophthalmoscope revealed double optic atrophy. The right arm and leg were extensively paralysed. On April 2nd, 1890, Dr. Bond opened up the mastoid cells, and removed some post-nasal growths. On admission to St. Mary's, Mr. Juler reported double optic atrophy, with a small amount of central vision in the left eye. There was marked deafness in the left ear. The right upper limb was paralysed, mostly in the hand and forearm. The right leg was similarly affected. Both limbs were wasted and colder than on the left side. The urine contained no albumen and no sugar. On May 30th, 1890, with Dr. Broadbent's sanction, I trephined over the left temporo-sphenoidal lobe, and also over the cerebellum, but no abscess was found. Hernia cerebri formed at the former site. It was removed on Sept. 23rd, 1890, after which it re formed to a less extent. The patient left the hospital unrelieved on Jan. 11th, 1891. A few months later he died, but unfortunately no necropsy was made. This case demonstrates *inter alia* how insidiously disease of the middle ear and temporal bone may progress. Commencing blindness was noticed about the same time as the aural mischief, the special symptoms of which were submerged, as it were, by the graver phenomena. There can, I think, be no doubt that had the mastoid bone been trephined early the lad might have escaped his subsequent troubles.

Deep suppuration in the neck may owe its origin to disease of the middle ear or mastoid bone. An abscess forming external to the mastoid process may of course burrow widely and deeply, but I wish now to direct attention especially to a class of cases in which it commences at a greater depth. The local inflammation may extend either through the Glasserian fissure, in which event the temporo-maxillary articulation is very liable to suffer; or it may lead to perforation of the mastoid bone through the digastric fossa. Here the pus, meeting with the juxtaposed occipital artery, is conducted by it to the carotid sheath, along which it spreads. It is prevented from coming to the surface by the superjacent muscles and dense fascia.

J. K——, aged twenty-one, was admitted into St. Mary's Hospital on Sept. 22nd, 1890. He had had purulent discharge from the right ear as long as he could remember, but had suffered no inconvenience until a month before he came under my care. During that time he endured intense pain in the head. On admission his temperature was 105·8° F., accompanied with rigors. There was a tense swelling beneath the right sterno-mastoid muscle. No tenderness over the mastoid bone or temporo-maxillary joint. An incision an inch and a half long was made over the middle of the sterno-mastoid, and a large quantity of fetid pus evacuated. The abscess cavity reached from the base of the skull to the clavicle. His temperature next day was 97·5° F. Two days later a subgluteal abscess formed, probably pyæmic in nature; this was opened and drained. The patient left the hospital well on Nov. 3rd.

Recurrent external mastoid abscesses, in consequence of insufficient opening and drainage, may form at long intervals, the patient meanwhile remaining exposed to more serious complications.

E. M——, aged fifteen, was admitted to St. Mary's Hospital on July 16th, 1891. Seven years previously an abscess

Digitized by Google

formed over the left mastoid process; a second developed in the same situation twelve months since. Both healed completely, and, except for deafness and discharge from the ear, her health was good. Five weeks before admission suppuration again occurred. On the latter date pus was escaping from the meatus and also from a sinus over the bone. She was very deaf in the left ear. The posterior wall of the meatus was necrosed. I scooped out the mastoid, perforated the necrotic wall of the meatus, and passed a drainage-tube from the meatus to the opening made externally. She was discharged cured on Aug. 8th.

Necrosis of the posterior wall of the meatus has a special significance, inasmuch as the fungating granulations—sometimes described as polypi—forming around the dead piece of bone block up the passage and hinder the escape of pus from the tympanum and mastoid antrum. So long as the sequestrum remains, although the granulations may be completely removed, fresh ones spring up very rapidly, the patient thus obtaining only a brief respite from pain. Through the kindness of my colleague, Mr. Field, I assisted recently in removing a piece of loose bone from the ear of a lady, which had caused intense agony from the condition just referred to.

Implication of the temporo-maxillary joint is by no means infrequent in disease of the middle ear. It is usually associated with widespread affection of the mastoid. The inflammation extends through the Glasserian fissure or between the bone and the cartilage of the pinna. There is stiffness of the jaw, inability to open the mouth properly, and swelling over the head of the bone. Owing to the looseness of the articular capsule a quantity of fluid can be accommodated in the joint, and hence fluctuation is often obtained quite readily. It is of the greatest importance not to mistake an abscess working up by the side of the joint for synovitis of the latter. The former is diagnosed by the extreme throbbing pain and tenderness, and by the amount of swelling, which is more diffused than that from a distended capsule. Of course, inflammation of the joint may be purulent, in which case more or less permanent fixity is to be feared. If the synovitis has not passed beyond the stage of serous exudation, it mostly subsides very quickly after an adjacent abscess has been laid open. The following case, for which I am also indebted to Mr. Field, shows the force of the foregoing remarks.

Mr. B—— caught cold five months before he came under my notice, resulting in tympanic abscess, which perforated the drum. About four months later an abscess formed over the mastoid bone. This was opened, but the symptoms generally did not abate. At this time there were difficulty in moving the jaw and a painful swelling over the head of the bone. On laying open the sinus over the mastoid an orifice, just admitting a small probe, was discovered in the bone, from which pus was slowly escaping. I trephined and let out a quantity of matter which filled the antrum and smaller cells. During this procedure the mastoid vein was wounded—an accident of no great moment,—but the bleeding was readily stopped by plugging. Although considerable relief was at first experienced, the pain and swelling about the jaw in a short time became worse. I detected deep fluctuation just in front of the joint, made an incision, and let out pus. A large portion of the zygoma was quite bared of periosteum; nevertheless, the patient made a rapid recovery, and the movement of the jaw became once more painless and free.

Sclerosing ostitis of the mastoid bone from chronic ear disease may prevent nature effecting an opening externally, and so increase the danger of suppuration spreading to the cranial cavity.

F. B——, aged about nineteen, deaf from childhood owing to disease of both middle ears. Latterly the pain in the left ear had been greatly aggravated. When seen in consultation with Mr. Field the pain over the mastoid was noticed to be much increased by pressure over the bone, although the soft parts were quite healthy. The pupil on the same side was dilated and fixed. The thick outer plate of the mastoid was removed with the trephine and a drop or two of pus set free. The new bone, which had largely encroached on the antrum, was like ivory. A drain was inserted. A fortnight later, as the pain was not alleviated, further operation was resorted to. With a Marshall's osteotrite the cavity in the bone was enlarged, and deep in the interior another abscess, holding only a drop of pus, was encountered. The pain soon afterwards ceased. The left pupil returned to its normal size. Noteworthy facts in this case are: 1. The temperature was raised but little above the normal. 2. That whereas in general the mastoid cells had been in great part obliterated by the new-bone formation, a tract of rarefying ostitis had absorbed the layer next the lateral sinus, the wall of which could be felt and the pulsation of the brain seen to be communicated to fluid injected into the cavity made by the operation. It is next to certain that had the patient been left to nature either thrombosis of the lateral sinus or cerebellar abscess would have ensued. M'Bride mentions sluggish pupils as a sign of intra-cranial irritation in chronic ear disease. In the case now narrated the pupil only on the affected side was dilated.

Wimpole-street, W.

SOME REMARKS ON DR. RUFFER'S LAST PUBLICATION ON THE DESTRUCTION OF MICRO-ORGANISMS BY AMŒBOID CELLS.

BY E. KLEIN, M.D., F.R.S.

IN THE LANCET of December 28th, 1891, there appears an abstract of a lecture delivered in the theatre of the Laboratories by my friend Dr. Ruffer, in which he criticises some remarks that I made in my lecture at the Royal Institution in February of last year concerning the insufficiency of Metchnikoff's theory of phagocytosis to explain immunity. It is chiefly these criticisms of Dr. Ruffer about which I wish to make here a few remarks.

On page 1433 Dr. Ruffer refers to a remark of mine as to the presence of phagocytes in the dorsal lymph sac of the frog, being insufficient to explain the immunity of that animal against anthrax after the injection into the lymph sac of the anthrax virus. What I said is this: "It must seem very extraordinary that this—viz., the presence of phagocytes—should be really a true explanation of the refractory state of the frog towards anthrax, considering that the bacilli, like other minute particles, when injected into the lymph sac would be absorbed and brought into the circulation in a few minutes, nay, seconds—at any rate some hours before the phagocytes have got into the lymph sac in *sufficient* numbers to do battle with the bacilli." I have italicised the word "sufficient," because, as will be seen presently, this is the essence of my remark, and it seems to have entirely escaped Dr. Ruffer's attention. Everyone who has worked with anthrax in the frog knows that if into the dorsal lymph sac of this animal, while in the normal condition, a large dose of anthrax material, containing hundreds of thousands of anthrax spores or anthrax bacilli, be injected, no anthrax disease follows, and everybody who has read Ranvier's "Traité Technique d'Histologie" knows that the lymph of the dorsal lymph sac of the frog, like all lymph, contains amœboid leucocytes. The question of importance for the theory of phagocytosis is obviously one of numbers of leucocytes present. Ranvier, who made this lymph the subject of special study, says (*loc. cit.*, p. 149): "La quantité de lymphe que ce sac en contient est très-variable suivant les circonstances; ainsi elle est en général presque nulle, si la grenouille a séjourné longtemps dans un endroit sec." Frogs kept in the laboratory never contain more than a few drops of lymph in the lymph sac, and the number of lymph cells, though great in the microscopic specimen, is insignificant if compared with the enormous numbers of spores and bacilli that can be, and have been, injected into the lymph sac of such frog without producing anthrax. It is therefore quite unnecessary for Dr. Ruffer to tell us that "he has found numerous phagocytes present in the normal lymph sac of the frogs he had examined." The point is not whether there are numerous leucocytes present in the lymph sac—which nobody disputes,—nor whether some of these leucocytes contain the bacilli—which also nobody disputes,—but the question is whether they are present in *sufficient* numbers to eat up and destroy the innumerable host of spores and bacilli injected, and whether the limited number of cells containing the bacilli is at all in proportion to the work. Surely Dr. Ruffer does not really maintain that spores and bacilli are not directly absorbed and carried into the circulation. He cannot mean to suggest that the number of cells containing the bacilli is at any time great, nor that the surplus of the spores and bacilli remain quietly lodged in

Digitized by Google

the lymph sac till, many hours later, a sufficient number of leucocytes have been attracted to the seat of battle. Similarly, when Dr. Ruffer states "that the absorption of solid particles introduced into the lymph sac of the frog took place by the agency of leucocytes," he does not mean that if he injects a quarter or half a Pravaz's syringe of salt solution containing in fine suspension vermilion granules, all the vermilion granules remain in the lymph sac and are swallowed up by the leucocytes, and that vermilion granules are not carried by the lymph stream directly into the blood. If he does mean all these things, then all I can say is that his statements are contrary to the facts

In connexion with Dr. Ruffer's view that the anthrax spores and anthrax bacilli introduced into the dorsal lymph sac are destroyed by the leucocytes, and by these only, I should like to know what he has got to say to the extended observations of Sanarelli[1] as to the germicidal action on anthrax bacilli of the cell-free lymph of the dorsal lymph sac, inside and outside the lymph sac of the frog.

A second criticism of Dr. Ruffer is this:—"In another part of his lecture Dr. Klein states the cells seem to possess a particular chemical attraction for the bacteria, such as is possessed by certain chemical substances. ..... Now, every experimenter, without exception, has spoken of the bacteria attracting the cells, and not the cells the bacteria." Here also Dr. Ruffer quotes my words in a wrong sense, or rather in a wrong connexion. That he misunderstood them is shown by the statement which he immediately afterwards makes—viz.: "Clearly it is difficult to explain why, if the cells attract the bacteria, thousands of cells should migrate to the spot where micro-organisms are present, whereas if the bacteria attract the cells, the emigration of leucocytes can be readily explained." Dr. Ruffer obviously refers to the phenomenon of leucocytosis produced at the seat of inoculation, whereas I referred to an entirely different matter, as will appear from the following.

Pfeiffer first proved by systematic experiments that certain chemical substances attract bacteria, others repel them, and Baumgarten[2] says that these facts observed by Pfeiffer have probably an important bearing on the movement of both the cells and microbes within the infected human and animal body. Surely it is quite permissible to say that just as certain chemical substances of the bacteria attract or repel leucocytes (see Buchner's recent observations), so also certain chemical substances present in the cells and tissues attract or repel the bacteria. Is it not a well-established fact that the spleen is an organ which pre-eminently seems to attract microbes introduced into the subcutaneous tissue, the lungs, or into the blood? In the case of malaria, relapsing fever, typhoid fever, in anthrax and tuberculosis, is it not the spleen which is the organ, *par excellence*, which seems to attract and to offer the most suitable nidus for the microbes? In the acute exanthemata it is the skin, in hydrophobia it is the central nervous system, and in certain forms of cancer it is the epithelial and endothelial structures. Surely it is permissible to assume that there are present certain chemical substances in these different tissues which act in a "positive chemiotactic" sense on these different microbes, and hence make these tissues the selected nidus for their existence and growth. In the numerous instances of psorospermosis under discussion at the present time, it is chiefly the epithelial cells which are mentioned as the tissues attracting especially these micro-organisms. In artificially induced tuberculosis the tubercle bacilli are not present in the blood, but find in the cells of the spleen of the lymph glands and of the bone marrow the most attractive localities. And it seems to me also justifiable to assume—say, for instance, for the lymph cells of the tonsils—of the Peyer's glands, and similar superficially situated lymphatic structures, that the tissue fluids, being inimical to the existence of bacteria that pass into the tissue from the surface, they (the bacteria) find in the cells some attraction, some chemical substance which suits them, and hence these cells, far from being the enemies of the bacteria, are, on the contrary, their places of refuge, for a time at any rate. This view seems to me just as feasible as Dr. Ruffer's view, that because these cells contain bacteria, therefore they are the chief and only bacteria destroyers. It is well established that in some acute and chronic infectious diseases the specific bacteria are lodged chiefly in the leucocytes or similar cells, in which they grow and which they ultimately destroy. In Koch's mouse septicæmia, fatal in one to three days, the leucocytes of the blood are crowded with the specific bacteria, and by these the leucocytes become destroyed; in bovine tuberculosis, in tuberculosis artificially induced in rabbits and guinea-pigs leucocytes and similar cells are the principal substances in which the bacilli settle, and in which they grow; in the tubercular form of leprosy the nodules are entirely made up of round cells in which the lepra-bacilli grow, and which cells become gradually destroyed by the bacilli; in Koch's Egyptian ophthalmia the pus cells principally contain the bacilli, and by the growth and multiplication of the latter the cells become gradually destroyed; in gonorrhœa the gonococci are principally contained within the leucocytes, and by their multiplication gradually produce disintegration of the cells; in swine erysipelas in the pigeon the liver capillaries contain numbers of leucocytes in which the specific bacilli are very numerously present, and which thereby swell up and gradually disintegrate. Do not all these facts prove that in these diseases it is the cells which attract the bacteria? It is these cells in which the bacteria grow and multiply, and it is these cells which ultimately succumb to the bacteria.

A third criticism which Dr. Ruffer makes, and which I am quite at a loss to understand, is this: "Dr. Klein states that it has been proved beyond question that when the blood of an animal immune against a certain disease was injected into a non-immune animal suffering from the same disease the development of the disease is stopped." I did not exactly say this, but that "it has been shown that if an animal susceptible to a particular disease be first infected with the bacilli causing the disease, and then into such an infected animal the cell-free serum or plasma of the blood of an animal refractory to that disease be injected, the development of the disease in the former animal is stopped or prevented." In saying this I referred in a general way to the well-known results of the numerous and carefully conducted experiments on anthrax published by Ogata and Tasuhara,[3] to those of Behring and Kitasato on diphtheria and tetanus,[4] and I ought now to add the important researches of Tizzoni and Cattani[4] with regard to tetanus.[5] These last-named observers show that the serum of the blood of dogs made immune against tetanus possesses a powerful antitoxic action against tetanus; moreover, quite recently they have actually succeeded in *curing tetanus* in the human subject by the injection of that tetanus—antitoxin. How in the face of all these observations Dr. Ruffer can say "there is not the slightest particle of evidence to show that the serum of an immune animal, when injected into another animal, acts in the way described by Dr. Klein" I must leave Dr. Ruffer to explain.

In conclusion, I should like to draw the attention of the readers of THE LANCET to the recent work by Buchner and his pupils, as summarised by Buchner in the *Centralbl. f. Bact. und Parasit.*, vol. x., Nos. 22 and 23. From this account it is evident that even that last part of the theory of Metchnikoff, to which this latter still clings to—viz., that the destruction of bacteria by the leucocytes *forms part* of the general process of destruction of bacteria in the tissues of a refractory animal—has lost its last foundation. The phenomena on which Dr. Ruffer in his lecture lays so much stress—viz., that in Rauschbrand in the rabbit the local leucocytes and the taking up of the bacilli by the leucocytes is an expression of the bacilli becoming destroyed by the cells, and that these recent observations of his have confirmed him in his "former opinion that the destruction of micro-organisms in living tissues is accomplished by the cells of the body, and by the cells only," receive in Buchner's experiments an altogether different, and it seems to me a more feasible, explanation; it is to the effect that the first and decisive inimical influence on the infective microbes in a refractory animal and in living tissues is due to *the chemical action of the tissue juices*, that this *precedes* the taking up of the microbes by the leucocytes, that this latter phenomenon is entirely dependent on the former, and without the former primary process phagocytosis is impossible.

[4] Centralblatt fur Bact. und Parasit., ix., No. 21; and x., Nos. 2 and 3.
[5] An error occurred in the printed account of my lecture, which error Dr. Ruffer is quite correct in pointing out—viz., that rabbits are not immune against tetanus; it ought to have been stated that the blood, not of immune rabbits, but of rabbits made immune against tetanus, was used for protective inoculation.

THE RESULTS OF MAJOR AMPUTATIONS TREATED ANTISEPTICALLY

IN THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE, DURING THE YEAR 1891, AND FOR A PERIOD OF THIRTEEN YEARS AND NINE MONTHS—VIZ., FROM APRIL 1ST, 1878, TO DEC. 31ST, 1891.

BY FREDERICK PAGE,

SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE; CONSULTING SURGEON TO THE FLEMING MEMORIAL HOSPITAL FOR SICK CHILDREN; LATE EXAMINER IN CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH.

DURING the year 1891, as will be seen from Table 1, eighty-three major amputations were performed upon eighty-one patients, two males, an adult and a boy, losing two limbs, in each case a thigh and a leg. This is the largest number of amputations performed in a year in the infirmary during the period I have recorded results—viz., from April 1st, 1878, to Dec. 31st, 1891, thirteen years and nine months; and I believe it to be the largest number that has ever been performed in the institution since its foundation in 1751, one

TABLE I.

Table of Major Amputations treated Antiseptically in the Royal Infirmary, Newcastle-on-Tyne, during the year 1891.

Operation.	Injury.			Disease.			Total.
	No.	Rec.	Died.	No.	Rec.	Died.	
Double amputations..	2	1	1	0	0	0	2

hundred and forty years ago. The mortality has been unusually high; for of the eighty-one patients operated upon eight died—9·8 per cent. The high mortality is accounted for by the nature of some of the accidents. Thirty-five of the patients, all males, were operated upon for injuries, and seven of them died, four within thirty hours of the operation from shock, two from blood poisoning, and one from delirium tremens. This is a mortality of 20 per cent. During a period of five years—viz., from 1883 to 1887—one hundred major amputations were performed for injury in the infirmary, and only four patients died. The amputations for disease have been very successful during the past year; forty-six patients were operated upon, and only one died—2·1 per cent. During the four years from 1888 to 1891, 138 major amputations were performed for disease, and five patients died—a mortality of only 3·6 per cent. It will always be exceedingly difficult in a hospital situated like ours to avoid for any lengthened period a comparatively high mortality from primary amputation, so very much depending upon the nature of the accident for which the amputation is performed. How much the mortality from traumatic cases depends upon the nature of the accident is realised by a perusal of the precise cause of the seven deaths which have occurred after amputation for injury during the year 1891.

PRECISE CAUSE OF DEATH.

Case 1.—Male aged twenty-nine; died thirty hours after primary amputation through the middle of the right thigh, and of the left leg at the seat of election, from shock. Railway smash.

Case 2.—Male aged thirty-two; died twenty-nine hours after primary amputation at the hip-joint, from shock.

Case 3.—Male aged fourteen; died twenty-two hours after primary amputation of the thigh, from shock.

Case 4.—Male aged thirty-one; died eighteen hours after amputation of the arm, performed fourteen days after a bullet wound of the forearm, from blood poisoning. Patient had septicæmia at the time of the amputation.

Case 5.—Male aged nine; died five hours after primary amputation of the leg, from shock. The boy had also a fracture of the pelvis and of the ribs and other internal injuries.

Case 6.—Male aged twenty eight; died eight days after primary amputation of the leg at the seat of election, from delirium tremens.

Case 7.—Male aged fifty; died seven days after primary amputation of the leg at the seat of election, from blood poisoning. Had been a heavy drinker.

Case 8.—Female aged twelve; died eight days after amputation of the thigh for tubercular disease of the knee-joint, from tubercular meningitis.

Table 2 gives the results of major amputations from Jan. 1st, 1883, to Dec. 31st, 1891, during which period I have recorded the precise cause of each death. Of the 527 patients operated upon 38 died—7·2 per cent.; 207 of the patients were operated upon for injury, and 23 died—11·1 per cent.; 320 of the amputations were for disease, and 15 died—4·6 per cent.

TABLE II.

Table of Major Amputations treated antiseptically in the Royal Infirmary, Newcastle-on-Tyne, from Jan. 1st, 1883, to Dec. 31st, 1891, a period of nine years.

Operation.	Injury.			Disease.			Total.

Wrist	7	7	0	0	0	0	7
Totals	272	237	35	415	395	20	687

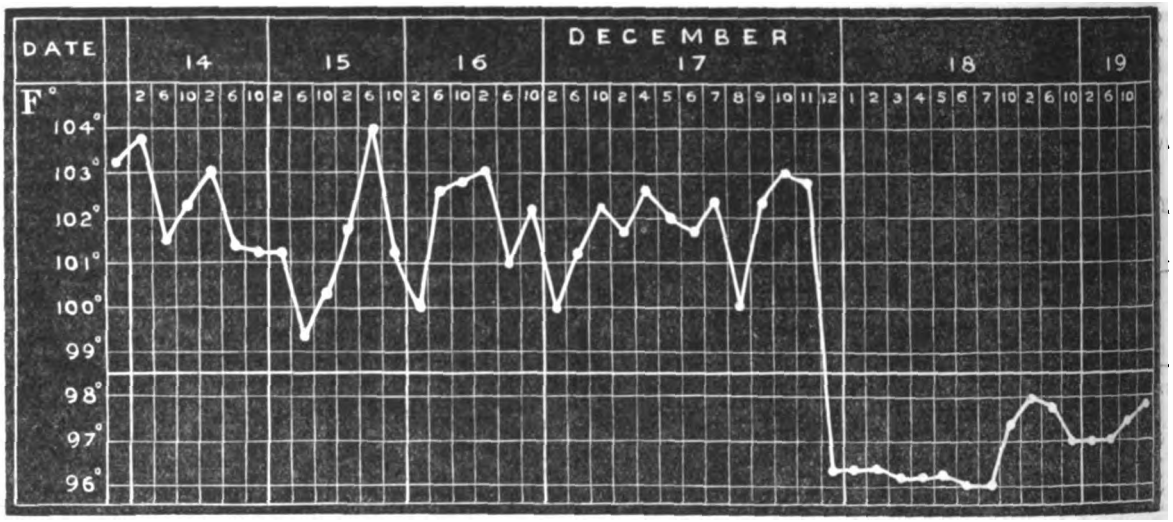
The total number is 687, with 55 deaths, a mortality of 8 per cent; 272 of the operations were for injury, with 35 deaths—12·9 per cent.; 415 were for disease, and 20 patients died—4·8 per cent.

Newcastle-on-Tyne.

ONE-HOUR CRISIS IN PNEUMONIA.

BY SAMUEL WEST, M.D.,

ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL.



ABRUPT as the crisis is in pneumonia, it proves on analysis to be hardly so sudden as it seems. In most cases the temperature does not reach the normal until after some hours. The average of one hundred cases, which I examined with especial reference to this point, proved to be twelve hours.

Digitized by Google

A crisis complete in eight hours was not frequent. The shortest in this series was of six hours' duration, and the shortest on record, so far as I know, lasted four hours. The present case is, I believe, unique, for in it the temperature fell from 103° to 96° in the space of one hour. I had been for some time interested in the fall of temperature during the crisis of pneumonia, and had given instructions that the temperature should in some of my cases be taken every hour, and it is to this that the observation is due. The patient was a lad of nine years of age, who had been in good health, except that he had once or twice in his life had a fit. On Dec. 13th, having been previously as well as usual, he was suddenly seized with a fit, and became very ill. Remaining unconscious and growing feverish, he was brought to the hospital, and was admitted. He was found with a temperature of 103°, pulse 110, and respiration 52, and proved to have left apex pneumonia. During the next twenty-four hours he had two more fits and remained deeply unconscious and delirious. For the next two days the patient continued in much the same state of delirium and fever, and the signs at the apex developed further. (See chart.) On the 17th—i.e., the fifth day of the disease—I gave orders that the temperature should be taken every hour. At eleven o'clock that evening the temperature was 103°, and at twelve o'clock 96·3, having thus fallen nearly seven degrees within the hour. The nurse stated that at eleven o'clock the patient woke up suddenly in what she thought to be a fright, and seemed to be extremely ill. At one o'clock when the house physician saw him, and confirmed the temperature taken by the nurse, the lad was sweating profusely, was less delirious, and seemed to be much better. The next day he was convalescent. Bronchial breathing continued until the 24th, after which the physical signs rapidly cleared up and he was soon quite well. If the pulse- and respiration-rate be followed, it will be seen that the crisis was preceded, as it so often is, by a drop in the pulse-rate, accompanied in this case by a drop in the respiration-rate also —16th: Pulse 120, respiration 60.—17th (morning): Pulse 96, respiration 56; evening, pulse 80, respiration 36 —18th: Pulse 68, respiration 32 —28th: Pulse 80, respiration 24. On leaving the hospital the pulse was 70 and the respiration 20.

A fall in temperature so sudden as this must be very rare; still, if the temperature can rise as suddenly as we know it does, there is no *a priori* reason why it should not fall as quickly. I have seen the temperature rise from normal to 108° in the course of twenty minutes. This occurred in a man of about thirty-five, upon whom a catheter had been just passed. Except for the stricture he was not supposed to be unhealthy. He died three days later, and proved to have granular kidneys. The physical difficulties of raising ten stone weight of living tissue ten degrees in twenty minutes are very considerable, and seem to require something almost of the nature of an explosive chemical decomposition, nor are the difficulties much less of cooling a weight of six stone of living tissue seven degrees in an hour. If the sudden rise seems to require some chemical decomposition, the sudden fall would seem to require the re-forming of some complex substance which had been previously split up. Rare as are the instances of such rapid rise and fall of temperature as those referred to, still account must be taken of them in any theory of fever which is to satisfy all the facts of the case.

Wimpole-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PERITYPHLITIS.

BY WM. TIPLADY, L.R.C.P., L.R.C.S.ED., L.F.P.S.G., &C.

ON Oct, 1st, 1891, I was called to see a child aged six years. On arrival I found the child very ill. Temperature 103°; pulse 120. Tongue dry, the knees drawn up, and vomiting incessantly, with pain in the umbilical region. Three days previously the patient had been riding on the back of an older girl, who had slipped and fallen backwards; hence our little patient had suffered from the fall and the weight of her companion as well. The fall had caused severe injury; for there were faintness, vomiting, and pain, which had never ceased till I was called in. On examination I could not make out any invagination of the bowel. There were no bloody evacuations, and no tumour could be detected; but there were intense pain, localised in the umbilical region, and tenderness so great that even the bedclothes were not permitted to touch the painful part. The effort to extend the legs from their flexed position caused great increase of the pain, and there was uncontrollable vomiting and constipation. Perityphlitis was diagnosed, caused by the fall.

The treatment consisted in enemata of warm water, which were successful in relieving the constipation, liquid nourishment, fomentations with turpentine, absolute rest, and opium in large doses. For a few days the patient remained more or less in the same condition, and the treatment was continued; but on Oct. 8th the patient was certainly worse in every respect. There was now diarrhœa, with a peculiarly fetid odour, and severe pain. Temperature 104°, pulse 130, tongue dry, and teeth covered with sordes. The abdomen was very tympanitic, respiration 50 and greatly embarrassed, and signs of collapse and approaching death. As a last resource, and the only hope in this desperate condition, I decided to open the abdomen in the median line, although the prospect of success was small. Hence a median incision was made, and upwards of a pint of pus with a peculiarly fetid odour was found. Evidently perforation of the bowel had taken place, for after pus fæcal matter came away freely, and continued to do so for some days. The whole cavity was well washed several

Digitized by Google

times daily with pure warm water. No drain was employed, but the wound left open, which was dressed with carbolised lint made into thick pads, and kept in position by a broad binder. The temperature fell, pulse improved, the pain disappeared, and, though the patient continued in a serious condition for a few days, improvement followed, and an uninterrupted and complete recovery took place.

Coupar Angus, Perthshire.

THE EFFECTS OF INFLUENZA UPON THE MIDDLE EAR.

By J. WALKER DOWNIE, M.B.,

FELLOW AND EXAMINER IN AURAL SURGERY FOR THE FELLOWSHIP OF THE FACULTY OF PHYSICIANS AND SURGEONS, AND SURGEON TO THE THROAT AND NOSE DEPARTMENT OF THE WESTERN INFIRMARY, GLASGOW, ETC.

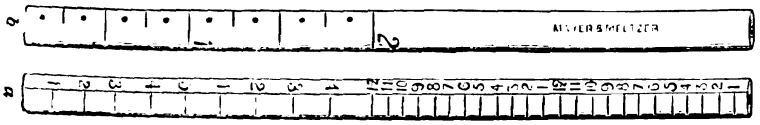
SIR WM. DALBY, in his "Note on the Effects of Influenza upon the Middle Ear' in THE LANCET of Feb. 20th, ends by saying that "a person with healthy ears has little to dread from influenza so far as this mucous surface [lining membrane of middle ear] is concerned; but it may become a serious trouble to one whose ears have formerly been the seat of inflammation." I fully agree with the latter portion of this opinion, founded by Sir William Dalby on his experience. Several cases similar to some of those described by him have been under my care, where an ear at one time the seat of inflammation, and bearing evidences of the inflammatory process—impairment of hearing, perforation of membrana tympani, &c.,—and which for many years had remained quiescent, again became acutely inflamed, and in some cases with markedly purulent discharge, as the result of influenza. The first part of the summary is not, however, according to my experience. We might suppose that those who have had scarlet fever and measles without suffering from tympanal inflammation might hope to escape such a complication when affected by epidemic influenza. But such is not according to my observation. I have lately had several cases in dispensary practice and in private of adults who previously had been free from any affection of the ears, but who during or immediately subsequent to an attack of influenza had acute middle ear suppuration. In all cases one ear alone was affected; in only one had I the opportunity of perforating the membrane, as in the others the membrane had been ruptured by the pent-up muco-pus very early. In the majority the ear became involved as the fever was abating. From reports I do not think that in Glasgow and neighbourhood influenza has been so general or so severe in character as experienced in London and other localities, yet I have seen a considerable number of cases of middle-ear inflammation following influenza in those who formerly had no "ear weakness," and thus I would take exception to Sir William Dalby's first conclusion, "that those with healthy ears have little to dread." Apart from implication of the middle ear, there have been several cases where symptoms closely resembling those associated with Ménière's disease have followed an attack of influenza. Those which came under my notice were associated with other symptoms pointing to the involvement of other nerve centres, but in one where deafness, giddiness, and ringing in the ears were the most marked signs, these disappeared as convalescence progressed.

Glasgow.

CHRONIC ARSENICAL POISONING.

By W. HARDING, M.B,

COUNTY ASYLUM, BERRY WOOD.



A GOOD example of chronic arsenical poisoning on a large scale occurred in this asylum, and a short account of it may be both interesting and instructive. In the endeavour to make the wards of an asylum bright and cheerful, and to do this at as little expense as possible, it is not improbable that the nature of the colouring materials used may be overlooked, and that some of the gastric and intestinal disorders which disturb the peace of mind of medical superintendents may be cases of arsenical poisoning. For a long period the nurses here were in poor health. First one and then another was laid down until, within a few months, nearly every nurse on the staff had been, or was, under medical treatment. Headache, neuralgias, gastric derangements, loss of appetite, constipation or diarrhœa, irritation of eyelids, anæmia—these were the chief symptoms complained of. Drugs did not appear of much avail, but a holiday had a marked effect for good. At last one nurse had the eye symptoms in a more pronounced form, and suspicion was aroused. In each nurse's room was a green baize curtain, used as a covering for dresses &c. A portion was taken and examined. It was found to be impregnated with arsenic to an astonishing extent. These curtains were removed; the rooms freely ventilated; medical treatment was stopped: the symptoms disappeared, and, though some months have elapsed, have not returned. The baize was similar to that used for covering doors &c., and was obtained from two manufacturers.

Berry Wood, near Northampton.

RULE AND SCALE FOR USE IN TREPHINING THE SKULL IN CASES OF AURAL DISEASE.

By H. MACNAUGHTON JONES, M.D., F.R.C.S. I. & ED.

IN operating recently in some cases of mastoid disease it struck me that a four-inch circular rule, marked in fractions of an inch, which the surgeon might carry in his pocket-case, would be of use in opening the skull, whether the mastoid antrum, the lateral sinus over the cerebellum, or the temporo-sphenoidal lobe. Also, that if he had with this a scale which would afford him an immediate guide to the exact spot on which to place the pin of the trephine, it would be of great value in assisting his memory in cases of emergency. Accordingly I had this rule and thin scale made of ivory by Messrs. Mayer and Meltzer as shown in the engraving.

The rule is one-fifth of an inch in its largest diameter, and four inches in length, and is marked in fractions of $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{3}$, and $\frac{1}{16}$ of an inch. The thin flat scale contains on one side the guides to trephining the skull, as laid down from the careful and exhaustive investigations of Dr. Ambrose Birmingham.[1] On the reverse side are the explanations of the marking. Such a rule and scale can be used not alone to ascertain the relative distances from the meatus, but also to guide the surgeon as to the depth to which the trephine is carried—an important point, as shown by Dr. Birmingham, in opening the antrum, not alone with regard to the lateral sinus, but also from the proximity of the external semicircular[2] canal, "which is in some cases not more than seventeen millimetres from the surface."

Harley-street, W.

GUIDES TO TREPHINING THE SKULL (*Birmingham*).

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SEAMEN'S HOSPITAL, GREENWICH.

TWO CASES OF COMPOUND SEPARATION OF THE SUPERIOR EPIPHYSIS OF THE HUMERUS.

(Under the care of Mr. W. JOHNSON SMITH.)

THESE two cases of compound separation of the upper epiphysis of the shaft of the humerus exhibit examples of a rare surgical injury. The upper epiphysis, including the two tuberosities, is not united to the shaft until the age of twenty, and it is not very uncommon to meet with simple divulsion of this epiphysis in the accident wards of our large hospitals below that age. The treatment of this injury is admittedly a difficult one, probably the most difficult of those affecting the upper end of the humerus. In a case reported by Dr. F. W. Murray he found it necessary to excise three-quarters of an inch of the shaft, and Lange has made known a similar case. Mr. Johnson Smith's cases show the amount of violence necessary to produce compound separation of the epiphysis and the good results which may be obtained by treatment. The ultimate result in the first case is especially noteworthy; for although it appears that nearly two inches and a half of the shaft were excised, sufficient new bone was formed from the periosteum which remained, and from the separated ends, to compensate for about one inch and a half of this, and form a bone apparently perfect.

Compound fracture of the right humerus at the junction of the shaft and the upper epiphysis.—John F——, an Irish boy aged fourteen, was admitted on August 18th, 1891, with an injury to the right shoulder, complicated by protrusion of bone through a wound in the axilla. All that could be learnt as to the cause of this injury, which had occurred about half an hour before admission, was that the right sleeve of the patient's coat had been caught in some machinery, and that the arm had been violently wrenched. The boy when first seen in the ward was pale and collapsed. The injured arm was abducted and rotated outwards. There was much swelling over the outer side of the shoulder. In the outer boundary of the lower third of the axilla there was a transverse wound about two inches and a half in length, through which protruded the upper end of the shaft of the humerus detached from the head. This protruded portion of bone, which was two inches in length, was completely denuded of periosteum. The upper surface, which was also quite bare, was even over its anterior third, then rose into a small rounded elevation, and shelved off obliquely to the posterior surface of the bone. The anterior half of the surface was smooth, and presented a continuous layer of compact bone tissue, whilst in the posterior half the spongy tissue was exposed, as if a small portion of the upper end of the shaft had been broken away. There was no bleeding from the wound at the time of admission, and the patient's clothes were but slightly stained by blood. On examination of the seat of injury, whilst the patient was under the influence of ether, it was found that the protruded end of the humerus had passed between the median and ulnar nerves, and that one surface of the bone rested upon and firmly compressed the main artery. The denuded portion of the shaft of the humerus was thrust through the wound in the axilla and sawn off. The detached portion from which the periosteum had been stripped away measured two inches and a half in length. The shortened end of the shaft then fell back into the axillary space, and rested very near to the head of the bone. The capsule seemed to be intact, and no orifice could be found leading into the joint. As there was much swelling in front of the shoulder, it was found impossible to make out whether or not the long tendon of the biceps had been ruptured. A drainage-tube having been thrust to the bottom of the wound, this was closed by sutures, and the seat of injury covered by a large wood-wool pad. A firm pad was placed in the axilla, and the upper limb bandaged to the side of the chest.

The patient progressed favourably after the operation. During the first three weeks the recorded temperature was usually normal and never higher than 99·5°. The wound healed slowly, but without any discharge of pus. The movements of the arm were much restricted for some weeks, but when the boy was discharged on Oct. 13th were quite free. He could then lift the limb a little above the level of the shoulder and move it to the full extent in the forward and backward directions. The movements of rotation were much restricted.

On Jan. 12th, 1892, the patient was again seen at the hospital. The movements of the right arm were then quite free in every direction, and this limb, the boy asserted, was as strong and useful as the left one. There were no signs of muscular atrophy, and no appreciable difference could be observed in the thickness of the two limbs. Repeated measurements were made of both arms from the tip of the acromion to the external condyle, but shortening of not more than one inch could be made out on the right side. The right shoulder was rounded, and did not differ in external appearance from that on the opposite side. There was clearly firm union between the head and the shaft of the bone. The boy had since the middle of November earned eight shillings a week by manual labour, consisting mainly in his moving heavily laden wheelbarrows.

Distortion and uselessness of arm after compound fracture through the upper epiphysial line; operation.—W. L——, aged eighteen, a Danish seaman, was admitted into the Seamen's Hospital on Jan. 28th, 1891. On Nov. 16th, 1890, the patient fell from the topsail yard on the deck, injuring his head and left shoulder. He stated that there was a large wound in front of the joint, through which protruded a long piece of bone. This in the course of the voyage, which lasted till Jan. 26th, gradually fell back into the wound, and was covered over by scar. There was no medical man on board the ship, and the patient was treated simply by rest and the application of ointments to the wound. At the time of the patient's admission the left upper limb as compared with the right was wasted and cold. He could move the limb freely at the elbow and wrist, but the movements of the shoulder were much retarded. He could move the elbow away from the side of the chest to the extent only of about an inch and a half. The length of the left arm, measured from the acromion to the external condyle, was eleven inches and a half; that of the right arm twelve inches and three-quarters. In front of the shoulder, beginning about two inches below it, was a broad, irregularly shaped cicatrix, measuring three inches in the vertical direction. Immediately beneath this was a prominent hard projection, formed by the upper end of the shaft of the humerus displaced inwards and forwards. The upper end of this portion of the bone, which had evidently been detached from the head, was smooth and slightly rounded. The head of the humerus seemed to be in its normal position. After attempts had been made without success to restore the free action of the shoulder-joint by passive movements, ether was administered on Feb. 17th, and the prominent portion of bone exposed by a vertical incision about four inches in length. The anterior two-thirds of the upper end of the shaft presented a free surface, which was quite flat and smooth. The posterior third, on the other hand, was united to the anterior and inner portions of the upper segment of the humerus, and the posterior and outer surfaces of the shaft near its upper end had contracted firm osseous union with a long piece of bone continuous with the head or the anatomical neck. The union between the two segments of the humerus having been severed by bone forceps, and a portion of the posterior spine of bone removed, the upper end of the shaft was applied to the under surface of the head and fixed in position by a loop of thick wire, and also by an ivory peg driven through the anterior surface of the shaft into the cancellous tissue of the upper segment. The wound, having been drained and closed by superficial sutures, was covered by cyanide gauze and a large pad of wood-wool. The patient did well after the operation, and was discharged on May 17th, quite free from any deformity in front of the shoulder, which joint the patient could move very freely, and, according to his own report, as well as that on the right side. In a letter written in August last he stated that he had been at work for some time as a seaman, earning £6 a month.

YORK COUNTY HOSPITAL.

CEREBRAL ABSCESS SECONDARY TO EAR DISEASE; TREPHINING; DEATH.

(Under the care of Mr. JALLAND.)

THE symptoms pointing to the presence of pus in the temporo-sphenoidal lobe were very few in this case, some of the more important being absent. During the first few days after admission the restless, excited condition of the patient prevented any examination of the discs, and when examined shortly before operation nothing abnormal was noted. The case illustrates well a sequence of events commonly found—chronic disease of the middle ear, with discharge of purulent nature, the formation of a polypus obstructing the meatus, caries of the temporal bone, and cerebral abscess. The marvellous way in which respiration returned after having ceased for some time, as the pus was evacuated, was the cause of surprise to those who were present at the operation. As permission was only obtained to examine the head, it is not possible to say exactly to what extent the fatal result must be attributed to cerebral abscess or may have been due to other disease. For the notes of this case we are indebted to Mr. J. B. Lendrum, house surgeon.

R. C——, aged nineteen, was admitted into the York County Hospital on Jan. 16th, 1892. The patient first came to the hospital on Dec. 17th, 1889, with otorrhœa and a history of deafness and otorrhœa for ten years. He was treated with injections of boric lotion. Then his hearing was: right ear, 1½ in.; left, 1½ ft. He remained under treatment for five weeks. He came again on Jan. 12th, 1892 (Tuesday), with a fresh attack. Two days later he complained to his parents of great pain over the right side of the head, which increased, and on Saturday about noon he became delirious, and seemed to have convulsions of some nature, not confined to any special part of the body. He was admitted at 7 o'clock P.M. the same day (Jan. 16th). His temperature was 99·4°, pulse quick and full. Patient sensible, but he lay in a condition of "cerebral irritation," on the left side, with the knees drawn up. He complained greatly of pain over the left side of the head and across the brows. Tenderness on percussion over the left side of the head; otorrhœa; pupils slow to reaction of light, but not markedly abnormal. The attitude of general flexion found to be the patient's usual attitude in bed. Temperature at 10 P.M. 102°.

Jan. 20th.—For the past three days patient has been much in the same irritable condition; temperature at an average of 99°; pulse varied from 82 to 72; respiration 24 to 16. Blister ordered to be applied over mastoid process. Provisional diagnosis of meningitis. In the afternoon the temperature rose to 101°, but fell at 10 P.M. to 99·4°.

21st.—Temperature varied between 99·4° and 100·8°; pulse 64; respiration 18.

22nd.—Patient felt much better, was quite rational, had slept well, and the pain was not marked; appetite good; wished to get up. Pulse fell to 54; temperature between 98·8° and 99·2°.

23rd.—Temperature between 98·8° and 97°. At night patient complained greatly of pain along the back of the neck, sitting up in bed and crying out loudly at intervals. The pulse dropped to 48; temperature 97°. Had a quarter of a grain of morphia given early in the evening; at 12.30 P.M. another sixth of a grain. Slept lightly afterwards from 4 A.M. (Jan. 24th) to 7 A.M.

24th.—About 7 A.M. the patient began to get restless, and developed a divergent squint in the right eye for a short time, but at 9 A.M. had passed into a semi-comatose condition. Pupils of normal size, insensible to light. Slight reflex in orbicularis palpebrarum on pinching the cheek. Breathing rather stertorous; patient lying on his back. At 10.30 he was seen by Mr. Jalland, who recommended trephining. Temperature 96·4°; pulse 70.

At 12.30 the operation was performed under chloroform, as reflexes to pain were not abolished. Crucial incision, half-inch trephine applied one inch and a half above and half an inch behind the meatus auditorius externus. While this was being used the patient suddenly stopped breathing and became very cyanosed. The pupils became widely dilated. The chloroform was stopped and artificial respiration done. Ether injected subcutaneously, and an amyl nitrite capsule used. There was a great quantity of mucus at the back of the pharynx. The heart, which was beating vigorously at the early stage of the cyanosis, gradually became weaker. Respiration not being resumed, it was decided to continue the operation, which was done while artificial respiration was carried on. A fine exploring needle was passed through the dura mater rather backwards into the brain, and between one and two ounces of very fetid pus came out. Gradually natural respiration returned, so the artificial respiration was stopped after twenty minutes. The pupils became much more contracted, the right being still the larger. A small drainage-tube was passed into the abscess cavity in rather a posterior direction, and the skin stitched up. Dry dressings were used and 10 minims of ether given hypodermically. At 3 P.M. the patient was sleeping; both pupils were equal, and contracted; corneæ sensitive. He had expectorated about half an ounce of mucus. Pulse rather jerky, but strong—102 to the minute. Temperature 97·4°. 9 P.M.: Wound dressed. No purulent discharge; no fetid odour; wound looked well. Temperature 100·2°. 12 P.M.: Temperature risen to 100·8°. Pulse very rapid, 140 to 160. Respiration quick, 44. Mucus had again accumulated at the back of the throat. Patient sleeping with eyes half open. Corneal reflexes and sense of pain present. Unable to swallow; suppositories and enemata given.

25th (12 noon).—Temperature dropped from 102° to 100·8°. Pulse still 140-160. Right pupil again larger than left. Eyes wide open, and seem to be attracted by an object held in front of them. Patient mumbled something inarticulate on being spoken to. A polypus was removed from the right auditory canal and the canal syringed. 6.30: Stitches removed. A trocar was put straight in at right angles to the surface, and some fetid pus drawn off. Slight immediate improvement in condition of breathing. 7 P.M.: Patient quite comatose. Pulse hardly perceptible; heart still feebly beating; respiration very slow, shallow, laboured, and irregular—not Cheyne-Stokes type; temperature 105°. 7.30: Death from asphyxia.

Necropsy.—Venous congestion of pia mater over whole of brain (asphyxial?), no meningitis, no local adhesions of pia to dura mater. Perforation below right temporo-sphenoidal lobe, size of sixpenny-piece, in communication with, but not adherent to, a much smaller perforation in the dura mater on the anterior surface of the petrous bone. Orifice at side of temporo-sphenoidal lobe due to drainage-tube healthy. An abscess in temporo-sphenoidal lobe, size of small hen's egg.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Phagocytosis.

THE adjourned discussion on Phagocytosis was continued on Tuesday, March 1st, Sir George Murray Humphry, F.R.S., President, in the chair.

The discussion on Phagocytosis and Immunity, which was adjourned from the last meeting, was resumed by Dr. J. SYER BRISTOWE, who approached the subject from a clinical point of view. He showed that the resistance of the body to the invasion of infective diseases was provided for in various ways—(*a*) mechanical, as the opposition of the skin and mucous membranes; (*b*) by inflammation, with subsequent encapsulation or suppuration; (*c*) by active warfare or phagocytosis; (*d*) by unfitness of soil &c. With regard to *c*, he agreed with Dr. Burdon Sanderson's position as stated at the last meeting. Should the infective principle succeed in getting past these first barriers they would enter the system along the bloodvessels or more commonly along the lymphatics as far as the first group of glands. He thought that cure occurred by the infective principle getting beaten at the mucous membranes or at the lymphatic glands, but these modes of spontaneous cure would not include the cure of the exanthemata after their generalisation, and it was in these cases especially that immunity most frequently arose. He then contrasted various types of infective diseases, taking tubercle, diphtheria, typhoid fever, and small-pox as types of the different varieties. Local skin tubercle or lupus, instead of producing general tuberculosis, seemed to prevent it. In diphtheria and typhoid fever the chief symptoms were associated with the local lesions rather than with the generalised poison, which as a rule produced its effects after the subsidence of the local lesions. With small-pox and the other exanthemata the conditions were

wholly different. Taking inoculated small-pox as an example, the poison appeared to be developed for nine days with formation of the pustule and enlargement of neighbouring glands, then the generalised condition set in with eruption on the third day. Immunity seemed to be acquired in the earlier stages of the disease, as it was remarkable that whilst the pocks were developing the poison from them was not absorbed by the body, probably the pocks were really cut off from communication with the rest of the body by phagocytosis, and the inflammation which surrounded them. By vaccination the generalised disease that was produced and which gave immunity was comparable to the invasion period of small-pox, but he could not say how the immunity was caused. He suggested that it might be possible to avoid the local ill effects of vaccination by injecting the lymph deeply into the tissues or into the glands.

Dr. WILLIAM HUNTER opened his remarks by pointing out the essential difference between phagocytosis and the "humoral theory," the one attributing the defensive power of the body against micro-organisms to cells, the other to the serum of the blood and other fluids. To establish the second theory it was insufficient to employ destructive criticisms against the first, as had been attempted. The arguments adduced arranged themselves in two groups: (1) those affecting the inherent probability of either theory, and (2) those affecting the accuracy of data. The chief principle involved was that one form of protoplasm should be able to take up another weaker form and destroy it. It was a matter of common inference that one immune individual had some new power enabling him to overcome micro-organisms gaining access to his blood, and it had been the practice of late to express this condition in terms of cells instead of in terms of individuals. He urged that no new property of cells was insisted on, and that in his opinion it was more logical to attribute these powers to cells than to the fluids of the body. Apparently the most offending claim of the new doctrine was in elevating special cells to this important function. This, however, commended the theory to his acceptance. Acquired immunity consisted, he thought, in an alteration in the constitution and action of the cells of the body. And he quoted experiments which tended to show that certain substances which appeared to exert much influence on the blood plasma did so really only through the medium of the spleen cells, and it was a remarkable fact that an animal could tolerate double the dose of an ordinarily fatal bacterial poison after removal of this organ; and he argued that if the spleen had such an important influence, it was highly probable that cells in the blood had the same. He thought that the arguments adduced in favour of phagocytosis added much to our knowledge with regard to immunity, and afforded the best working hypothesis, whereas the humoral theory added practically nothing, and was based on a great deal of assumption. Photo-micrographic slides were exhibited which were demonstrated to illustrate the effect of chemiotaxis, as shown by the varying quantity of leucocytes entrapped in shavings of sponge, soaked in certain toxic agents, and inserted under the skin.

Dr. MARTIN then spoke of natural and experimental immunity, indicating that the latter alone in which conditions were regulated and controlled would bear accurate investigation. He thought that anthrax which had been most completely worked out afforded the best indications. With this it was well known that, after vaccination with an attenuated virus, a sheep subsequently inoculated did not die. Was the reply to this the statement that the leucocytes so altered killed the bacilli introduced? He had shown that the chemical products of the attenuated bacilli were identical with those of the virulent ones, both as regards albumoses and albuminoids. On the other hand, he had found that whereas the virulent bacilli flourished in a suitable medium, the attenuated ones dwindled and died, and also that the products of the latter were less in quantity than of the former, the difference being one of *degree* rather than of *kind*. Both depended for their action on their chemical products, and the paradox was presented that the attenuated organism prevented the action of the virulent one, though giving rise to the same products. The explanation of this was that injection of the attenuated virus accustomed the animal to the chemical poison in a manner similar to that known in connexion with poisonous drugs. In pursuance of this idea Dr. Martin quoted experiments showing that the injection of ten milligrammes of the albumose products of anthrax growth preceding the insertion of one cubic millimetre of "splenic mash" enabled the animals to live four days, and a half, the "controls" not surviving twenty-four hours. In another series, in which the bacterial products and "splenic mash" were mixed together and injected, the animals lived twenty days, and did not then show signs of disease except in the spleen, the effects being regarded as an imperfect imitation of those attending an attenuated virus. It seemed that the chemical products of these micro-organisms remained a long while in the body; for, though the fever attending a single dose of anthrax albumose lasted only five days, the animal went on wasting for from ten to twenty-four days. As to why the micro-organisms did not develop in immune animals, it could hardly be supposed that the products of previous vaccination remained in sufficient quantity to hinder the growth of the fresh bacilli. And it was far more reasonable to suppose that these products exerted a profound influence on the blood, which supplied the pabulum on which the organisms subsisted. In this connexion, he drew attention to the remarkable sensitiveness of bacilli to the culture medium, the micro-organisms requiring a proteid capable of digestion—salts, including phosphates of sodium, calcium, and magnesium, and sodium chloride,—and being unable to thrive either in the presence of an excess of phosphates or deficient sodium chloride. In the body it was the blood which supplied this medium, the solid tissues not being adapted for their development, possibly because of the non-suitability of their constitution in these respects. It could hardly be stated yet what actual changes the toxic substances produced, but it seemed pretty evident that they resulted in immunity. With regard to the contest between leucocytes and bacteria, it was one between nucleated protoplasm and protoplasm capable of producing a chemical poison. The experiments which had been performed were, he thought, inconclusive, and those whose effects had been exhibited by Dr. Hunter would bear quite a different explanation. There was injury to tissues, and the albumoses themselves were capable of exciting inflammation without attributing to them special "chemiotaxic" powers.

Dr. WRIGHT referred to Wooldridge's work in connexion with "chemical protection" afforded by the injection into the blood of crushed thymus or testis, and which he attributed to the action of tissue fibrinogen. Experiments had been made which showed that anthrax subsequently introduced had a very modified effect, so that such animals frequently survived. Want of uniformity in these results had been due to defective methods of sterilisation. The idea of chemical protection and the employment of tissue fibrinogen had been taken up by Hankin, who attributed to it bactericidal power. He also obtained a body—the so-called alexine—from the spleen of the white rat, believed to be immune against anthrax, which he injected into guinea-pigs previous to inoculation with anthrax, with the result that four survived and in two life was prolonged as compared with "controls" out of six. The experiments had been repeated with similar results. This "alexine" was apparently the same as Wooldridge's tissue fibrinogen, in which anthrax was capable of developing. An examination of blood after injecting tissue-fibrinogen showed that the number of white corpuscles was at first diminished, and then increased. The preparation "nuclein," an apparently similar body, was known to increase white corpuscles 40 to 50 per cent. in an hour. The idea of producing artificial leucocytosis was applied, and found to prolong life in cases infected with anthrax. These bodies should be regarded as *cell stimulants*, and though at first employed for their direct effect on the bacteria on the humoral theory, really supported that of phagocytosis.

Mr. J. G. ADAMI said that for considerations of brevity perhaps the best method of attacking this subject of immunity was to start with the best and most complete series of observations in the case of one disease, observations that were both recent and reliable, and then accepting the facts so gained, to observe how they opposed or confirmed the various theories which had been brought forward. For this purpose he would select the very full and pregnant research of Klemperer and Klemperer upon pneumonia. The results of these observers might briefly be stated as follows:—1. Immunity against pneumonia can be bestowed upon susceptible animals by introducing into the tissues the sterilised products of growth of the pneumococcus. This immunity is in general but of a

temporary nature. 2. Such immunity, induced by injections of bacterial products, does not immediately manifest itself; indeed, fourteen days must elapse before the simple products bring about their effects. But if the sterilised products be heated either to 106° F. or 107·5° for from three to four days, or to 140° for two hours, then injections induce immunity within four days. 3 The warmed "vaccine" leads to a reaction of but short duration; the unwarmed brings about a long-continued febrile state, at the end of which the animal becomes immune. 4 Thus the fever, with its elevation of temperature, and the antecedent heating of the vaccinal material, induce the same result; one or other process would seem to be necessary in order that sterilised bacterial products develop immunity. 5 But, further, the blood serum of a "protected" animal injected into the veins of a susceptible animal confers immediate immunity. There is no delay. Evidently, therefore, some substance is present in the blood serum of an animal made immune, a substance not present in the sterilised culture fluids of the pneumococcus; the bacterial products, therefore, do not *per se* bring about immunity, but through the febrile reaction some other body having immunity-conferring properties is gradually developed. 6. What is more, this same substance has curative properties acting not so much on the pneumococci themselves (for in its presence these continue to proliferate), but upon the poisons or toxines manufactured by them. 7. Hence Klemperer and Klemperer distinguish two proteids—the pneumotoxine, which can be isolated from cultures of the pneumococcus, and the anti-pneumotoxine, to be obtained from the serum of immunised animals It was unnecessary to dilate upon the way in which this work of the two Klemperers fulfilled and elucidated the previous observations of Salmon and Smith, Christmas, Roux, and Chamberland, Hankin, Bouchard and his school, Brieger and Fraenkel and others upon bacterial products; of Wooldridge, Christmas, Hankin, Buchner, Hankin and Martin, Tizzoni and Cattani, and Fraenkel upon proteid bodies capable of inducing immunity, and, in the case of some of these observers, upon the anti-toxic properties, as opposed to the bactericidal properties of such proteids. Nor was it necessary to do more than point out the light that these observations threw upon the meaning of the febrile state. Evidently, as shown by a large number of recent studies, the phenomena of infection and immunity are at base chemical; certain substances are produced by the bacteria on the one hand, by the organism on the other, whose action is of a chemical or chemical-physical nature. But now came the question: How was this action exerted within the body? Were bactericidal and anti-toxic substances normally free in the blood, were they developed within special cells, or were they generally distributed throughout the tissues of the body? In the first place, it could not be too strongly insisted that their presence in blood serum was no certain indication of their presence in blood plasma. Blood serum and blood plasma exhibited marked differences in their characters, and nothing was more marked than this difference in the bactericidal powers of the two fluids. An animal which was most susceptible to a given disease had time after time been shown to yield a serum capable of destroying large numbers of the micro-organisms causing that disease; and, at the risk of repeating what was well known to many, he would again call attention to Lubarsch's classical observation that whereas 10,000 to 12,000 anthrax bacilli are all that can be injected into the circulation of a rabbit without causing a fatal disease, one cubic centimetre (fifteen minims) of a blood serum of such a rabbit will in a few minutes destroy the same or a much greater number of the bacilli. While he was far from convinced that under no conditions the plasma can become bactericidal or anti-toxic, he still thought that sufficient satisfactory evidence had not yet been brought forward in support of the humoral theory. The cases mentioned by Professor Klein were not without flaw; the rapid diminution of the number of bacteria present in arterial or venous blood is not conclusive evidence that these bacteria have undergone destruction in the blood plasma (phagocytosis being as yet undeveloped). Professor Klein and the humoralists have to bring forward surer proof than has yet been adduced that the bacteria as foreign bodies have not been arrested in the capillaries of various organs, and that the diminution of their number in the circulating blood is not caused by such a filtration process. Again, while he was prepared to admit freely that bactericidal and anti-toxic substances may appear or be developed in the cells forming many of the tissues of the body, he held that it has yet to be proved that this can obtain to any great extent. We were still without proof that, save in the case of organs formed largely of leucocytes and potential phagocytes, the tissue can have powers at all comparable to those possessed by the serum and body fluids. We were therefore driven to the third possibility—namely, that the difference between serum and plasma depended upon an alteration in the condition of the white corpuscles, and that the leucocytes were a most essential factor in the production of immunity. There was not time here to bring forward all the arguments in favour of this view, but this he might say: what other interpretation was to be placed upon, not simply the engorgement, but the enlargement of lymphatic glands, the enormous increase in the number of white corpuscles in the blood in zymotic disease (under conditions to be referred to later), the determination of leucocytes towards regions of bacterial invasion, unless it be that the leucocyte plays a most important *rôle* in protecting the organism? It is true there were conditions in which it was wanting. In pneumonia, for example, Tchistovitch had shown where the virus was not very powerful, there an increase occurred; where the virus was very strong, there a diminution was to be made out in the leucocytes of the blood. The same occurred in regard to the amount of diapedesis resulting after local invasion, this depending upon the virulence of the invading organism. Taking into consideration general rather than local injections, we learn that the leucocytosis is dependent upon the reaction of the organism to the soluble products of the virus. That the leucocytes can possess bacteria-killing powers was supported by Hankin's observations upon the lymphatic glands and spleens of refractory animals, in which he showed that from those organs, composed as they were largely of mature and immature leucocytes and the parent cells of the same, could be obtained a bactericidal substance acting specifically upon the microbes to which the animal was refractory. It was impossible for him to criticise Dr. Woodhead's objection to this—namely, that Dr. Wright has grown micro-organisms freely upon leucocytes, until the conditions of these experiments had been fully described. To come now to the assumption of bactericidal powers by blood serum, he remarked that, as Rauschenbach had shown, and as a matter of common experience, coagulation of the blood and production of serum was accompanied by a great disintegration of certain of the white corpuscles,[1] and he suggested that to this disintegration was due the presence of bactericidal substances in the serum. Just as from fresh blood and intact white corpuscles no fibrin ferment was obtainable, so it might be that the intact leucocytes did not *normally* contain bactericidal substances, but precursors thereof. Possibly this was fitted to explain Dr. Woodhead's contention with reference to quinine. He was unwilling that this working hypothesis, whereby he had attempted to reconcile for the time being the divergent results of a host of capable workers, should be dubbed a theory; still more did he regret that it should have been accredited to him. For while he had worked it out along his own lines, its origin was to be found in Mr. Hankin's work, and to all intents and purposes this was the hypothesis brought forward by Hankin at the International Congress last year. If for no other reason, he was glad to join in this evening's discussion in order that honour might be given where honour was due. Lastly, as to the way in which the leucocytes acted upon the bacteria, he could not help being impressed by the fact that the more perfect the methods employed, the greater was the phagocytosis observable in the course of resolution of disease; and he concluded that, even though leucocytes had other methods of acting upon bacteria and their products, phagocytosis was a most important—probably the most important—factor in the production of immunity. Professor Burdon-Sanderson's main objection, that leucocytes were to all intents and purposes independent organisms, and that therefore they could not reasonably be expected to act in accordance with the needs of the organism, was, it seemed to him, based on the idea that leucocytes were generation after generation propagated in the blood, free from the fixed cells of the body. But this was scarcely the accepted view. Very little mitosis of the leucocytes occurred in the blood, whereas the characteristic mitotic areas in the lymph glands offered an almost certain indication that the proliferation

[1] Upon these points see the fuller details given by Dr. Wright in last week's LANCET.

Digitized by Google

of leucocytes occurred in regions where the parent cells might be regarded as fixed and capable of being influenced by nervous and other stimuli. It is to these parent cells rather than to the free, motile leucocytes, with their short span of life, that we must look to explain continued powers of resistance to bacterial products on the part of leucocytes, the development of increased resistance, the development of immunity.

Mr. T. J. BOKENHAM gave the results of some investigations on erysipelas which would have to be explained before the question of the causation of immunity could be settled. (*a*) Different effects of injecting cultures of true streptococcus erysipelatis into rabbits and guinea-pigs. Inoculation of a virulent culture into a rabbit's ear produced a typical spreading erysipelas without pus formation, though the lymph, whilst the process was advancing, was very rich in leucocytes. If some of this lymph be injected into a guinea-pig and another rabbit, the latter will contract a disease in every respect similar to that in the first rabbit, but nothing will happen to the guinea-pig. (*b*) Alteration of virulence of streptococcus erysipelatis under varied conditions. If a culture of streptococcus erysipelatis too attenuated to produce the disease in a normal rabbit be injected into one into which a simultaneous intra-peritoneal injection of a sterilised culture of bacillus prodigiosus had been made, typical erysipelas would appear at the point of inoculation. In this case, a rabbit which was immune to an erysipelas of a low virulence was made susceptible, and inoculation from it to a normal one would produce the typical disease in the second, and by continuing the process through successive rabbits a very virulent form of erysipelas could be produced, in which a highly infective disease occurred with generalised symptoms, though no reaction occurred at the point of inoculation. Here, undoubtedly, the local cellular infiltration seemed to have played some part in the localisation of the disease. If a rabbit vaccinated against the bacillus pyocyaneus be inoculated with streptococcus erysipelatis, a general fatal infection occurred without local reaction at the seat of inoculation, but blood from this rabbit could only produce the local disease in a normal rabbit in association with attenuated erysipelas, while a common mould increased the virulence of the streptococcus both generally and locally.

The following card specimens were exhibited.—Dr. CHAS. SLATER: Cultures and Preparations of Leprosy Bacilli.

MEDICAL SOCIETY OF LONDON.

Diagnostic and Prognostic Value of Tubercle Bacilli in the Sputum.—The Influence of Intra-nasal Obstruction on the General Health.

AN ordinary meeting of this Society was held on Feb. 29th, the Vice-president, Dr. Stephen Mackenzie, in the chair.

Dr. F. J. WETHERED read a paper on the Diagnostic and Prognostic Value of Tubercle Bacilli in the Sputum. Since the discovery of the tubercle bacillus in 1882 by Koch much had been written in regard to the value of a search for this organism. He wished to make a few additions to what had already been published on the aid to diagnosis furnished by the tubercle bacillus from his own experience, and also to comment on its prognostic signification. As to the method of staining, after trial of several methods he had always reverted to the Neelsen-Ziehl process of staining in a carbolic acid solution of fuchsine and decolourising in a 25 per cent. solution of sulphuric acid. The chief points to which attention should be directed to procure successful results were: to select the early morning sputum; to pick out the small opaque particles; to stain for two minutes in the heated stain; to thoroughly take out the red stain with the acid, a quarter of an hour not being too long, although a minute was usually sufficient; finally, to counter-stain in methylene blue. There were still some medical men who viewed with a considerable amount of scepticism the value which was to be attached to the presence of tubercle bacilli in the sputum; but the various papers which had been published had conclusively proved their true value. Roughly speaking, a positive result—that is to say, their presence—was absolutely diagnostic of a tubercular process going on somewhere in the respiratory tract; but a negative result, their absence, was practically of no value. It was in those cases in which the history and physical signs were not clear enough to warrant a diagnosis of tubercle that a bacteriological examination was of value, especially when phthisis was masked by bronchitis or emphysema. In obscure laryngeal cases it was also of value, as a differential diagnosis from syphilis might thus be established. A negative result did not by any means absolutely exclude phthisis, even though several examinations of the sputa might have been made. As regards prognosis, he had come to the conclusion that little could be learnt from the numbers and distribution of the organisms. The mere fact of their presence naturally increased the gravity of the case, but beyond this he did not think it was safe to go, the general aspect of the case being a surer guide. He had found bacilli to be very few when the disease was progressing rapidly, and to be numerous when the patient was recovering. Examination of unstained specimens would often lend aid, and especially ought the leashes of elastic tissue to be carefully sought for.—Dr. HADLEY urged the importance of using absolutely clean slides, having found bacilli perfectly stained in slides washed for some days in spirit and potash. The organisms were discoverable in preparations which had been steeped for twenty-four hours in 25 per cent. sulphuric acid. He thought that when bacilli were found, specimens of elastic tissue could always be obtained. By the new methods of staining, however, the bacilli were the more easy of discovery. He agreed as to the difficulty of finding bacilli in miliary tubercle, even when squeezing out the actual miliary granules.—Dr. CHAPMAN recommended spreading the sputum on the slide instead of on the cover-glass, and insisted on the inefficiency of anything below one-twelfth or one-sixteenth objective.—The VICE-PRESIDENT asked the author of the paper as to his experience in finding tubercle bacilli in fibroid phthisis.—Dr. WETHERED, in reply, said his experience in fibroid phthisis was not large, but the cases he had examined did not furnish them. Apart from a caseous nodule or calcareous particle, it was difficult to distinguish between fibroid phthisis and fibroid pneumonia.

Mr. SPENCER WATSON read a paper on the Influence of Intra-nasal Obstruction on the General Health. Starting with the text that in many forms of disease, not obviously of nasal origin, patients have been cured or relieved by treatment directed against nasal stenosis, Mr. Watson gave a brief epitome of the functions of the nose as part of the respiratory tract, and drew attention to the varieties of stenosis as (1) Partial, (2) Complete, (3) Temporary, (4) Permanent. In some cases headache, migraine, and perhaps some other symptoms are due to the obstruction of the apertures of the sinuses opening into the nasal cavities, and other nerve symptoms result from sleeplessness as an indirect result of stenosis. Asthma is sometimes associated with stenosis, and is cured by local treatment. Operations of a complete character at one sitting are more likely to relieve asthma than a succession of small repeated operations. Hay asthma is not to be regarded as a simply intra-nasal disease, though often aggravated by nasal complications. The most common forms of stenosis—viz., snuffles in infants, adenoid vegetations, and chronic hypertrophic rhinitis, with or without polypi—were then described, and the treatment by the author's ring knife and by the wire snare recommended as applicable to many cases of the last-named diseases. Cases were related, and drawings of specimens shown. The conclusions were as follows: (1) That by suitable treatment directed against stenosis we may in young children prevent convulsions, deformity of the chest with its concomitant evils, and in some cases even prevent death from marasmus; (2) that in youth and early life by relief of stenosis we may prevent permanent deformity of the chest, deafness, impairment of speech, and even of the mental faculties; (3) that in adult life we may prevent, and in some cases cure, by the relief of nasal stenosis, asthma, spasmodic cough, bronchitis with its complications, and various mental disturbances.—Dr. DE HAVILLAND HALL differed from the author in preferring to operate under an anæsthetic, more particularly cocaine. In reference to hay asthma, he thought that if deep scarring were effected in the mucous membrane by means of the galvano-cautery there was no need for more severe measures. This method served also in cases of paroxysmal sneezing; this, however, in combination with general treatment. He alluded to the occurrence of enuresis, which was said by German authorities to be cured by removal of the obstruction, and to the frequency of hernia. These points, however, were not in accord with his own experience.—Mr. SCANES SPICER mentioned, in connexion with nasal obstruction, the occurrence of anæmia and a possible predisposition to phthisis.—Mr. SPENCER WATSON replied briefly, pointing out the cases which required a general anæsthetic.

CLINICAL SOCIETY OF LONDON.

Separation of Epiphysis of Head of Femur.—Myxœdema.—Microcephalus.—Sarcoma of Face and Neck.—Hæmoglobinuria and Gangrene.—Cholelithiasis.—Pachymeningitis Hæmorrhagica treated by Trephining.—Rhachiotomy.

A "CLINICAL" MEETING of this Society was held on Feb. 26th, Sir Dyce Duckworth, President, in the chair.

Mr. DAVIES-COLLEY exhibited a case of Separation of the Epiphysis of the Head of the Femur in a lad aged fourteen, who presented, however, a considerable range of movement.

Dr. ARTHUR DAVIES showed the fourth case of Myxœdema he had met with in the course of five years. The disease was of seven years' duration, in a woman of forty. She had all the usual signs, with fatty cushions above the clavicles, albuminuria, and a diminution of urea to 1·5 per cent.

Dr. HADDEN exhibited a case of Microcephalus in an infant affected with rigidity of the limbs and retraction of the head. The parents were healthy, but there had been exposure of the mother to three distinct frights during the early months of gestation. The fontanelles were apparently closed at birth.—Dr. WALLACE ORD and Dr. LEES showed similar cases, and the question of craniectomy was raised.—Dr. JONES of Earlswood, referring to adults, said the prognosis was pre-eminently gloomy. Under these circumstances he thought an operation was permissible. He discarded the idea of maternal impressions, and said that such cases formed nearly nine-tenths of those in Earlswood Asylum. Vaulting of the palate was absent, the children were usually bad tempered, and progress was slow. He referred to a post-mortem examination he had made on an adult case, in which the occipital lobes were defective and there was flattening of the angular gyrus. Many cases became epileptic. An operation had been performed in four cases, but he was not aware with what result.

Mr. DUNN showed a lad on whose face and neck large masses of new growth (? Sarcoma) had formed. There was also ulceration of the palate. Portions had been removed and exhibited the structure of sarcoma. He was losing weight.

Mr. W. SPENCER exhibited a case of Hæmoglobinuria and Dry Gangrene in a boy who had slept for three nights out in the cold. There was a history of his being liable to pass bloody urine on exposure to cold, but none of cold extremities. The lesion he submitted was of the nature of frost-bite.

Mr. BLAND SUTTON communicated the details of a case in which a woman aged fifty-eight, suffering from gall-stones impacted in the common duct, was submitted to operation. After opening the peritoneal cavity the liver was found obscured by dense omental adhesions. The gall-bladder was shrunken, and contained three polygonal calculi, but no bile. No communication existed between the gall-bladder and the common duct. After carefully separating adhesions from the under surface of the liver, the common duct was detected blocked with four calculi. Two were firmly fixed at the duodenal orifice of the duct. The remaining two slipped into the hepatic duct, but could not be passed into the gall-bladder as the cystic duct was obliterated. Various attempts to move the calculi impacted at the duodenal orifice failing, the duct was incised close to the wall of the duodenum and the stones extracted; one of the stones pushed into the hepatic duct was not recovered. A glass drainage-tube was inserted, and the wound in the skin sutured in the usual way. On the evening of the tenth day following the operation the remaining calculus probably passed into the duodenum. The jaundice rapidly disappeared, the track of the drainage-tube closed, and the patient left convalescent after a sojourn of twenty-five days in the hospital.—Mr. ERNEST LANE mentioned a case of five weeks' duration, giving a history of a blow on the abdomen followed by abdominal distension. On cutting down, an enormous flow of bile took place from the peritoneal cavity. He had since had a letter from an Italian surgeon, who had satisfied himself that the idea that bile was poisonous to the peritoneum was erroneous.—Mr. STANLEY BOYD referred to Knowsley Thornton's method of breaking calculi up by means of a needle passed through the duct wall.—Mr. HULKE related a case in which the symptoms were typical, but where, on cutting down, he found a tangled mass of omentum in which was the gall-bladder contracted on a group of calculi. Though he felt convinced there must be some in the common duct, he was obliged to relinquish the attempt to liberate them. The patient died ten days later, and there was an opportunity of confirming the diagnosis.

Mr. STANLEY BOYD read an account of a case (under the care of Mr. Johnstone Harris) of Injury to the Left Side of the Head and Concussion, in which almost all symptoms, except occasional headache and lack of energy, disappeared in two to three weeks, and the patient, believing himself well, returned to work as an innkeeper. After seven weeks of apparent health he developed in about ten days right hemiplegia, commencing in the arm and spreading to the leg; at the same time he became more and more drowsy, and finally almost comatose, whilst his temperature rose to 102°. He was trephined with the view of evacuating an abscess, which was supposed to occupy the right arm-centre; but in place of an abscess a cystic clot containing about four ounces of clear, dark-red fluid was found, emptied and drained. Consciousness was not regained for several hours—perhaps because the walls of the cystic clot were somewhat rigid, and prevented expansion of the brain. Both the right limbs began to move on the day after the operation. The patient passed through an attack of delirium (*e potu?*) lasting several days, but finally made a perfect recovery. The opinion was expressed that the clot found was not an immediate result of the injury, but that, more probably, it was due to cortical hæmorrhage beginning about the time of the onset of the late symptoms. It was, however, pointed out that this view did not fully explain the final *rapid* increase of the insensibility.—Mr. OPENSHAW alluded to a patient admitted three weeks ago into the London Hospital. He had left-sided convulsions, beginning in the left hand. There was a history of a fall on the head a week previously, evidenced by a laceration of the scalp. It was decided to trephine. Four or five ounces of blood-stained serum and clot came away on cutting through the dura mater. The patient made a rapid recovery. In two cases of the same kind the pupil on the same side was dilated.—Mr. BLAND SUTTON thought the fissure alluded to by Mr. Boyd must be an ordinary fissure fracture. He came to this conclusion because there was no bevelling, no sutures, and no Wormian bones.—Mr. JOHNSTONE HARRIS said the diagnosis was easy, but he had expected to find evidence of an inflammatory lesion. He thought that there was probably a second extravasation to account for the deepening of the coma so long after the accident. He did not think the case threw much light on the pathology of subdural extravasation.

Mr. N. DAVIES-COLLEY showed a female patient aged twenty-three, a laundrywoman, unmarried, who was admitted into Guy's Hospital in July, 1891, with paraplegia and, what was then thought to be, angular curvature of the dorsal spine. The disease began seven years previously, after a fall. She had been comparatively free from pain &c. for some time, and had resumed her occupation. Two months before admission she had pain in the chest and back, followed by weakness and loss of sensation in her legs, with some incontinence of urine and fæces. On admission the patient, who was fairly well nourished, had a large rounded projection over the spines of the fourth, fifth, and sixth dorsal vertebræ. After three weeks' rest in bed, as her condition was gradually getting worse, Mr. Davies-Colley cut down and found that the tumour was due to a spindle-celled sarcoma growing from the lamina on the right side of the spine. It was removed with some difficulty, together with the spines and laminæ of the fifth and sixth dorsal vertebræ. The spinal cord was soft, but the dura mater appeared to be healthy. Complete recovery followed in respect of both sensation and motion within six weeks. Mr. Davies-Colley insisted upon the difficulty of distinguishing such a case from one of ordinary spinal curvature, and advocated the use of the term "rhachiotomy" instead of laminectomy.

EPIDEMIOLOGICAL SOCIETY.

JOSEPH EWART, M.D., President, in the chair.

WEDNESDAY, FEB. 17th.

Is Influenza etiologically distinct in Man and Animals?

DR. ROBERT SISLEY read a paper under the above title, and began by remarking that, apart from and between the epidemics of imported influenza, there were from time to time local outbreaks of a disease very similar, if not identical, in its phenomena. One such had been described by Sir Peter Eade as having occurred in Norfolk in 1879 [illegible]

there were numerous notices of the kind in French and German medical literature Tessier, after a careful inquiry, had come to the conclusion that influenza was endemic in Russia, or at least never absent for many months from one part of the country or another. Horses, it was well known, were very liable to a disease or diseases known as influenza, but there was no doubt that the term was often applied to purely catarrhal affections. Indeed, the ambiguity of the expression was considered by the Academy of Medicine of Paris so great that they declined to investigate the question of the identity of the human and equine disease until the veterinary surgeons had come to some agreement as to what they meant by the name. In England, on the contrary, Dr. Sisley considered that the veterinarians were in advance of the medical profession—at any rate, in having long since recognised the specific and communicable character of influenza. Drs. Clemow, Copeland, and Creighton, and Professor Fleming, had recently done good work in this field, and he had collected from their writings the materials for two tables showing in chronological order the years in which epidemics or epizootics of influenza had been recorded. The former list was carried back to a much earlier date, but during the three or four centuries covered by both it would be seen that they sometimes corresponded, though frequently epizootics appeared alone, as more rarely did epidemics, from which some would conclude that there was no real connexion between them. But the carefully collected evidence brought together in this country by Sir J. Caird and Drs. Hartley, Parsons, and Bruce Lowe, and by Tessier and Ollivier in France, was almost irresistible as to the fact that, though rarely, it was so transmitted. In Caird's case there was no influenza among the human population of the district, but a number of horses in a most insanitary stable were suffering when a dancing class of forty children from the villages and homesteads scattered over several square miles met in the loft above and communicating with the stable. Thirty-three of the children were simultaneously attacked, as well as the men in charge of the horses.

The PRESIDENT remarked that at Brighton the horses, especially those in large establishments, had suffered severely some weeks before the epidemic had reached its height; indeed, the omnibus and cab service was completely disorganised. But a brewer who had no fewer than forty horses, by simply giving strict orders against their being allowed to drink at the public troughs, had succeeded in keeping his stables entirely free.

Dr. CLEMOW had not formed any opinion on the question of influenza in the lower animals; though sceptical as to the identity of the disease, and feeling the want of scientific discrimination among veterinary surgeons, he admitted the force of the evidence adduced by Dr. Sisley and the need for fuller future investigation.

Dr. WILLOUGHBY said that, though he had given considerable attention to the etiology of human influenza, he had no experience of the disease among the lower animals, and at present maintained the same attitude of scientific scepticism as Dr. Clemow. He would like to know if the enlargement of the spleen, which was as constant in human influenza as in enteric fever, and belonged to it as a specific disease, had been noticed post mortem in horses or cats, as it would be almost conclusive evidence of identity. If not, he hoped that Dr. Sisley would not fail to look to it.

Dr. SISLEY, in reply, promised to do so, as he was not aware of any such observations having been made. He agreed with Dr. Willoughby as to the immunity, if any, conferred by one attack being very feeble.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Medical Section was held on Feb. 5th, Dr. J. M. Finny in the chair.

The Dietetic Treatment of Enteric Fever.—Dr. WALLACE BEATTY read a paper on the dietetic treatment of enteric fever. He laid great stress upon the importance of care not only as to the nature, but also as to the quantity of food. He considered from two to three pints of milk in the twenty-four hours ample nourishment for enteric fever adult patients during the entire illness. He believed that patients who were fed on such a restricted diet suffered much less from diarrhœa, tympanites, and sleeplessness than patients more liberally fed. He called attention to the fact that when from some cause, such as threatened hæmorrhage, the diet of patients had to be much restricted, a general improvement in all the symptoms followed. He advised extreme care in the manner of changing the diet at the approach of convalescence; a sudden change from liquid to solid food was, he believed, likely to provoke a fresh outburst of fever and bring on a relapse.

A Case of Recurrent Enteric Fever followed by True Relapse.—Dr. J. W. MOORE submitted a "clinical record" of a case in which not only did enteric fever recur in the same patient, but the recurrent attack was succeeded by a true relapse after an apyrexial period of eleven or twelve days. In April, 1877, the author attended, with the late Dr. Alfred Hudson and Sir George Owens, a lad of fifteen years, who passed through a typical attack of enteric fever lasting twenty-three days, in which, however, constipation, and not diarrhœa, was the rule. In October, 1891, the same patient, at the age of twenty-nine, sickened of a fever which proved to be undoubted enteric fever. After running an acute course of twenty-four days, followed by a subfebrile period extending over another week, this attack was succeeded by convalescence, which seemed to be in all respects normal. On the eleventh or twelfth day, however, from the establishment of apyrexia, acute febrile symptoms again showed themselves, and for the third time in his life the patient passed through an attack of enteric fever. The adjourned discussion on Dr. M. A. Boyd's paper on "Some Recent Modifications in our Views of Enteric Fever and its Treatment," which was read at the last meeting of the Section, was then opened in connexion with a discussion on the papers which had just been read.—The PRESIDENT criticised one or two points in the clinical history of the case described by Dr. Moore which occurred to him to need explanation. First, with reference to the significance of the diazo-benzole reaction. In his own experience—and he had applied the test almost daily to a large number of cases in Sir Patrick Dun's Hospital—he did not rely upon it as by any means a safe clinical test, either as to diagnosis or prognosis in fever, and he did not agree with Dr. Moore that the failure of the test was due in any way to the fact that his patient had had fever fifteen years before.—Dr. H. T. BEWLEY did not think the question as to relapses in typhoid fever could be solved until the whole question of immunity, natural and acquired, was more certainly known than it is at present—we do not know accurately why cases of infective fevers got well at all; possibly the greater tendency to relapse in typhoid fever as compared with such other fevers as typhus, scarlatina, and measles, was connected in some way with the long and irregular course and prolonged termination of the fever. With regard to giving solid food, in some cases of typhoid the fever will not decrease, and the patient grows weaker until solid food is given. It was difficult to say exactly when the time had come to give this solid food, and he would look anxiously for further information on this subject.—Dr. WALTER SMITH said that Dr. W. Beatty's paper was essentially a qualification or limitation of Graves' celebrated maxim.—Dr. LITTLE considered there could be no doubt of the value of a restricted diet in enteric fever; there could be no doubt of the value of milk when diarrhœa is present; but some patients are unable to digest milk, and especially if then danger arises from cardiac failure, he considered properly made animal broths more suitable than quantities of milk.—Dr. DOYLE also joined in the discussion.—Dr. BOYD in his reply to the criticisms on his paper on the antiseptic method of treating enteric fever, considered that so far no more rational method of dealing with the disease from its pathology presented itself, and notwithstanding Dr. Smith's doubts as to any disinfectant reaching the intestine in sufficient strength so be of use after passing through both stomach and duodenum, he thought if any form of antiseptic could survive unaltered, the gaseous one should—especially in a solution which slowly parts with it. Chlorine evolved from an alkaline solution—such as the liq soda chlorinate of B. Ph.—in his hands was followed by better results than when formed in an acid mixture. As regards the relapses in enteric fever, they seemed to him to be due in most instances to a fresh set of glands and Peyer's patches becoming the seat of fresh infection by typhoid bacilli. He lately showed an instance in a pathological specimen exhibited at the last meeting of a portion of the ileum, the seat of active ulceration in a patient who was ten days apyretic, when he died from acute perforation, the result of over-eating. This specimen showed how long a condition of ulceration may exist after typhoid fever, even when the

Digitized by Google

temperature has fallen permanently for as long as a week — In answer to Dr. Little, Dr. MOORE said that he sometimes gave small doses of quinine in enteric fever, not to reduce temperature, for fulfilling which object large doses alone would avail, but as a tonic from his experience of the remedy in other acute and prostrating maladies. Once the specific origin of enteric fever was admitted, Dr. Moore believed that no mere error in diet would bring about a true relapse, although it may be a contributory cause of such an accident.

Reviews and Notices of Books.

A History of Medical Education from the most Remote to the most Recent Times. By Dr. THEODOR PUSCHMANN, Public Professor in Ordinary at the University of Vienna. Translated and Edited by EVAN H. HARE, M A Oxon., F.R.C S.Eng., and L.S.A.Lond. London: H. K. Lewis. 1891.

THERE are two ways of writing the history of Medicine. One is to follow, in chronological order, the vicissitudes of the healing art, from its rude beginnings to its reduction to rational system by Hippocrates; from its abuse of the systematising spirit, with all its fatal excursions along "the high *priori* road," to its adoption of the inductive method, and its final settling down to the one true path on which alone it can advance—that of scientific research checked by clinical observation and experience. In this way, the history of Medicine has been well treated, mainly by continental scholars; and, in the classic works of Häser, Puccinotti, and Daremberg, the student may read in German, Italian, or French a comprehensive and trustworthy record of the rise and progress of the profession.

But there has long been room for another and more philosophic treatment of the subject. To consider medicine, like theology or law, in relation to the intellectual and moral movement of humanity from age to age; as reflecting no more and no less than the spirit, scientific and social, of the time; as advancing, pausing, or retrograding in sympathy with the civilisation of successive epochs: such is the way in which the history of medicine ought to be dealt with at the close of the nineteenth century. True, such a mode of treatment demands far wider knowledge and far more philosophic grasp than have yet been shown by either French, Italian, or even German scholars; but the possession of such qualifications is becoming an ever greater possibility, according as research throws up richer material to the surface, and as juster views of the march and meaning of history can be taken from a higher vantage ground commanding a wider horizon. Dr. Puschmann's work is a first attempt at this mode of handling the subject, and its success is such as might have been anticipated from a physician who is also a man of letters and a thinker of acknowledged accomplishment and power. Though scarcely three years old, it is already a classic; and, if not without defects, the lines on which it is laid are such as will readily admit of modification or supplement without sacrifice of its distinctive features.

Dr. Puschmann's method is indicated by his title, "The History of Medical Education"—that is, of all the intellectual and moral influences under which the medical mind is evoked, developed, and formed. Not only medicine itself, but the sciences in relation to which it stands, directly or remotely, come within his survey, and accordingly we never lose sight, all along the journey on which he leads us, of mathematics, physics, natural history, philosophy, and even government, civil and religious. This latter is shown to have had a powerful and too often a baneful influence on the academic teaching of medicine, putting its veto on anatomico-physiological research (dissection of the human subject, for example), and relegating to "empirici" the office of the surgeon by its long-continued discouragement of inquiry into structure and function.

In the domain of pre-Hippocratic medicine the most satisfactory section of the work is that on the Egyptian, thanks to the additions to our knowledge made by Ebers and other recent investigators. The healing art in China is left out, though even before the appearance of the work under notice missionary research had added a good deal to the meagre details disclosed to us. Nothing can be better, however, than his treatment of Hippocrates, to whose marvellous judgment and insight the author does full justice. The section on the Alexandrian school is masterly, showing a power of "reading between the lines" of Celsus such as has been given to few scholars. Indeed, the author's whole account of the Roman period is most interesting. Severus Alexander (not Alexander Severus), he reminds us, established public teachers of medicine, salaried by Government—a notable advance on the previous state of things, when the young aspirant had to attach himself to some popular practitioner and act as his assistant. In this connexion Dr. Puschmann refers to Martial's epigram describing the sufferings of the patient when doing duty as "object lesson" to a fashionable consultant, with an audience of a hundred students round his bed. But perhaps the most fascinating section is that in which he shows the influence, for evil and for good, of early Christianity on the healing art. The new religion encouraged the tendency, handed down from remoter times, to make book-study a substitute for post-mortem examination and experiment on the living subject; but it redeemed this error by its creation and diffusion of hospitals, in which its distinctive "caritas" went hand in hand with its multiplication of the means of clinical observation, whereby an experience was open to the young practitioner such as pagan antiquity could not furnish. The hospital system spread to the Arabs, who turned it to good account; but the collapse that befell the world in the early middle ages affected the healing art as it did every other intellectual interest, and not till we enter a new period, with the foundation of the Salernitan school, is medicine found to revive.

Salerno, at which lady professors—Trotula, Calenda, Abella—lectured side by side with those of the rougher sex, was followed in France by Montpellier, and in Italy by the addition of medical faculties to numerous universities. From this point Dr. Puschmann enters on a most instructive exposition of university expansion, showing how, in opposition to Church prejudice, anatomy, step by step, achieved recognition and a place in the curriculum; how pharmacy engaged the attention of students in compounding and dispensing; and how the beginnings of the modern clinique were laid. With the dawn of the fourteenth century the examination of medical candidates began to assume regular forms, though surgery and obstetrics were still regarded by the academic aristocracy as outside their cognisance, to be practised by privileged amateurs in whose families the *métier* descended from father to son. Then came the mighty Reformation era, which, following on the discoveries of Columbus and Copernicus, and grandly represented by Luther, made its renovating influence felt throughout Christendom in every intellectual and moral interest, that of medicine especially. Medical education quickly responded in sympathy with "the ampler ether, the diviner air," blowing fresh and free over all the parterres of Academe, till juster conceptions of the circulation of the blood were hazarded by Servetus, Colombo and Cesalpino (whom Dr. Puschmann strangely overlooks in this connexion), afterwards to fructify in the immortal demonstration of Harvey. Ambrose Paré superseded the barbarous operations of non-qualified surgeons by a really scientific and artistic use of the knife, and at the chief seats of learning the curriculum of the medical student gained rapidly in comprehensiveness and thoroughness. The medicine of scholasticism was now in full retreat, and all down the seventeenth

Digitized by Google

and eighteenth centuries we follow Dr. Puschmann in his excursions through the more civilised countries as these became rapidly endowed with new institutes and museums under able superintendents, where the mere rote-learning and rote-repetition of the "old masters" yielded place to living contact with the realities of life in health and disease, and where the physician and surgeon was being steadily trained into what he has become *par excellence—naturæ minister et interpres*. Intelligibly enough, Dr. Puschmann lingers at most length over the University of Vienna and the great medico-military school of the Kaiser Joseph II., and we cannot grudge the attention he bestows on that distinguished centre of professional education and practice. In the concluding section he deals with "medical teaching in modern times," and tells us much as to the methods and the means by which the nineteenth century keeps itself supplied with ever-fresh relays of duly qualified practitioners in every branch of the healing art. An excellent index completes the book, giving in alphabetical order a noble array of the men of "light and leading" to whom medicine first and humanity afterwards owe so much.

Dr. Puschmann's work is well worthy of translation into all the languages of Europe—into English especially, which, since the able work of Freind early in the last century, has (strangely enough) no historian of medicine to show parallel with the German Haser, the Italian Puccinotti, and the French Daremberg. Mr. Hare has performed his task with diligence and judgment, and, though we never miss the impression that we are reading a translation, we may congratulate him on the freedom and even elegance he combines with fidelity to the original. Here and there we detect him giving an imperfect or even erroneous English equivalent for the German. At p. 4, for example, "gründlichen" is not represented by "extensive"; and, p. 5, "Berechtigung" means something more than "significance." At p. 6, "bestätigen" is inadequately rendered "give form"; and surely, on the same page, "Ausbildung" might have had a less clumsy interpretation than "structure in the education." At page 24, in a quotation from the Iphigenia in Tauris, he avoids a blunder in Dr. Puschmann's Greek only to add one of his own. But these are small matters, which will receive attention in a new edition. More important are the omissions in Dr. Puschmann's original, which Mr. Hare, who "edits" as well as "translates" his author, might have supplied. We have referred to the silence in which Chinese medicine is passed over, and also to the exclusion of Cesalpino's name from the precursors of Harvey. A place should certainly have been found for Dr. Gilbert of Colchester, of whom Bacon was ignobly jealous; while Galileo pronounces on him an enthusiastic eulogy for his "concetto tanto stupendo" (of the magnetic polarity of the globe). A yet graver omission is that of Nobili and Matteucci, whom a countryman of Dr. Puschmann credits with the most valuable contributions to electro-therapeutics. In a second edition, we repeat, we expect to see these and similar defects repaired. Meanwhile we have nothing but praise for the work as a whole. It ought to find many readers, and to help, in some measure, to remove the reproach from the profession that it pays too little attention to history, that of its own rise and progress included.

Strophanthus Hispidus; its Natural History, Chemistry, and Pharmacology. By THOMAS R. FRASER, M.D., F.R.S., Professor of Materia Medica in the University of Edinburgh. Edinburgh: Neill and Co.

UNDER the above title Professor Fraser has reissued, in separate form, two communications which have previously appeared in the Transactions of the Royal Society of Edinburgh. After a brief historical introduction the author deals in the first part with the natural history and chemistry of strophanthus, and his descriptions of the various parts of the plant are illustrated by numerous well-executed plates. The fascinating accounts of its use in Africa as an arrow-poison will bear re-perusal, although they are now matters of rather ancient history. The botanical description is very full, and applies not only to the parts which have now been rendered official, but also to the root, stem and branches, leaves and flowers. While all parts are carefully described, the greatest attention is naturally lavished upon the follicles and seeds. Professor Fraser's work in determining the chemical composition of the seeds is familiar, and it leaves nothing to be desired in the full description of the various stages by which the separation and identification of strophanthin, strophanthidin, and kombic acid have been effected, together with the no less interesting account of the unsuccessful search for an alkaloid.

The second part is devoted to a study of the pharmacological action, details of experiments upon over 150 animals being given to determine not only the general effects in frogs and rabbits, but also the special actions upon the cerebro-spinal nervous system, the skeletal muscles, the heart, bloodvessels and general circulation, the lymph-heart, and the respiration. Professor Fraser is not content with printing the general results of his work, he takes the reader into his full confidence, and shows him the various tracings from which these results have been so largely drawn. The clinical history of strophanthus is the only element which is wanting to complete the picture, and it is unfortunate that from the uncertainty inseparable from all therapeutic investigations we can never hope for this to be given with the force and precision which characterise Professor Fraser's most valuable study.

The Year book of Treatment for 1892: a Critical Review for Practitioners of Medicine and Surgery. London: Cassell and Co.

THE "Year-book of Treatment" now has such a well-established position that it does not require detailed criticism. Its methods are well known, and most of the contributors have now settled down to a style of work which from experience they have found to be most satisfactory to those who wish for a concise review of the progress of the year in the various departments of medicine and surgery. There are only two new names amongst the contributors—viz., Dr. M. Handfield Jones, who is responsible for the section on midwifery, and Mr. J. Ernest Lane, F.R.C.S., who deals with the subject of venereal diseases, in the place of Mr. Alfred Cooper, F.R.C.S., who now takes charge of a new section devoted to diseases of the rectum. Dr. Berry Hart is no longer amongst the contributors; and Dr. Herman, who last year compiled the review of Midwifery, now treats of the diseases of women. In the present volume is to be found for the first time a "selected list" of new books, new editions, and translations, in which considerable space is allowed for French, German, and Italian works. Having thus mentioned the chief new features of the book, there is little more to be said, beyond remarking that the range from which material has been selected is, as usual, wide, and indicates considerable industry and the determination to make the Year-book as complete as possible. It is a little curious to note that of the twenty-one contributors, although fourteen are drawn from London medical schools, seven of these are from one school, and the remaining seven from three other schools, thus leaving a very large majority of the London hospitals totally unrepresented.

THE LANCET.

LONDON: SATURDAY, MARCH 5, 1892.

OUR readers will have observed that at a meeting of the Council of the Royal College of Surgeons of England held on February 11th the Council, in pursuance of a resolution passed on March 4th, 1889, proceeded to the consideration of the infraction of By-law xvii. by certain Fellows and Members in February, 1889, by issuing notices convening a general meeting at the College without the sanction of the Council. After considerable discussion, the Council resolved to defer the consideration of the matter to its next meeting on March 10th, and meanwhile to inform the Fellows and Members concerned of this intention. It may, we think, fairly be presumed that in this postponement the Council was influenced, at least in part, by a desire to leave the door open for a conciliatory adjustment of differences by affording to those who had been led by mistaken advice on technical points into a breach of discipline an opportunity of retracing their steps, making the *amende honorable*, and acknowledging the legitimacy of the authority bestowed upon the Council in the Charters and by-laws. Should this course be pursued, there can be very little doubt that all sources of irritation will soon be removed, and that harmony will be completely restored. That this will be the outcome of the struggle we are encouraged to hope by the letter from Dr. GEORGE DANFORD THOMAS, chairman and treasurer of the Association of Members, which appeared in our columns last week. Dr. THOMAS states that a special committee of the Association has been formed for the purpose of considering the position of affairs and obtaining the means of meeting the liabilities incurred by the secretaries and members of the committee who were made parties to the suit "STEELE *v.* SAVORY." "The question of an appeal against the judgment of Mr. Justice ROMER was proposed and carefully considered, and, after weighing counsel's opinion, the committee determined that no further legal action should be taken." This determination of the special committee not to appeal against Mr. Justice ROMER'S decision will meet with general approval; for, notwithstanding the voluminous evidence collected by the plaintiffs and the substantial justice of their pleas for liberty of meeting and discussion, the prospect of upsetting Mr. Justice ROMER'S interpretation of the law, summary as it was, must be regarded as extremely remote. Much as we regret the issue of the struggle, and fully as we recognise the inherent greatness of that attribute of Englishmen of not knowing when they are beaten, we must frankly acknowledge that no good end could be served by keeping up the strained relations between the Council of the College and the Members whose sympathies generally have followed the action of the Association. To remove all traces of conflict without for one moment abandoning the principles whose too zealous assertion led to the present situation of affairs is the proper course for the Association to pursue. The adverse decision on the special points raised in the pleadings does not in the least affect the soundness of the principles on which the demand for reform of the Royal College of Surgeons is founded, or diminish the claims of the Members of the College to a voice in its management and in the election of its Council. If it has any effect at all it intensifies those claims because it imposes upon the great constituency of the College the necessity of being governed by charters and by-laws which are from fifty to a hundred years old, and are therefore in direct antagonism with the spirit of the age. It also requires from the Members of the College generally a fresh and united effort for the purpose of freeing themselves from the fetters which deprive them of the liberty to which they are justly entitled. The recent action was at least a courageous effort to serve the whole body of the Members, and it has involved the promoters in expenses which ought not to be left to be defrayed by the few who happen to be legally responsible. First efforts in the cause of freedom are often unsuccessful, but they pave the way for future success; and such future success may be ensured if the Members of the College will bestir themselves and unite heartily to further the common cause. A large accession of members to the Association of Members ought to be the immediate result of a reparable reverse, an accession which would at once be a demonstration of the earnestness of the Members in their desires for reform and a welcome replenishment of the treasury of the Association. If each Member of the College would contribute a small sum, and support the committee of the Association in any steps which may be deemed desirable for the purpose of obtaining a due recognition of the Members' claims, the whole complexion of the contest would be changed. It will always be assumed by the Council of the College, as it has been hitherto, that the Association of Members represents but a few of the Members of the College, unless positive proof to the contrary can be produced, and this idea strengthens greatly the opposition to the most moderate concessions to the Members of the College. The strongest arguments have and will have no effect while they as a body display apathy and indifference. The very extent of the constituency renders it the more difficult to influence and to arouse, and it may be that an organisation of the Association is required which will make provision for provincial representation and the formation of branches in different parts of the kingdom. Whatever may be the proper measures to quicken the interest and engage the active coöperation of the Members of the College, we trust that the committee of the Association will take the subject into serious and early consideration. All who are interested in the reform of the College must sympathise both with the cause itself and with those who have fought the battle and find themselves burdened with costs amounting to £2000. We therefore trust that the Members for whom the struggle was commenced will respond to the appeal of Dr. DANFORD THOMAS, and, to use his words, will "by their generous assistance testify to the courage and self-abnegation displayed in the important contest" in which the plaintiffs were engaged on behalf of the Members generally.

A PARTICULARLY interesting article on the influences which affect the power of voluntary muscular contractions appears in the first number of the *Journal of Physiology*,

written by Dr. WARREN P. LOMBARD, Professor of Physiology in the Clark University, Massachusetts. The influence of surrounding conditions, or, as HERBERT SPENCER terms it, of our environment, is more or less distinctly recognised by all. To one man, light, fresh air, and freedom of movement, whether in the form of hunting, or fishing, or mountaineering, are essential to the enjoyment of life. To him the confinement and restricted activity of the literary student are insupportable. To another a free supply of food is an absolute necessity, whilst yet another will be happy on the grey peas and water diet of Friar TUCK. Some feel wine, or some substitute for it, and tobacco to be indispensable; others can cheerfully dispense with either or both. CHARLES DICKENS required the bustle and activity of a great city to stimulate him to his best efforts. WORDSWORTH preferred to commune with nature alone. But in every instance the influences of the great forces that surround us, as well as of the minor agents, may be traced in the vigour and energy with which the ordinary avocations of life are performed. There are fluctuations both of muscular and nervous power which are manifested in the quantity and quality of the work done, whether this be the production of a "Messiah" or of an "Alexander's Feast," or in some violent and protracted muscular effort. Dr. LOMBARD'S essay is an endeavour to ascertain what are the influences which determine the activity and fatigue of the central nervous mechanisms exciting the voluntary muscles to action. With this object in view, he made a series of experiments on the flexor muscles of the second finger of the left hand. The arm rested on a firm support, the first and third fingers were enclosed in closely fitting brass tubes, and a firm cushion was placed behind the knuckles; a leather collar was fastened round the second phalanx of the second finger, to which was attached a cord passing over a pulley, and supporting a weight of two or more kilogrammes. The movements of the finger and of the weight were recorded by an ingenious but simple apparatus on a revolving drum. Amongst the more interesting of the results obtained by Dr. LOMBARD were that, in the first place, the central nervous mechanisms become more quickly fatigued than the motor nerves and the muscles, for when voluntary contraction is no longer possible the muscles are still capable of contracting and of raising the weight when either the muscles themselves or the motor nerves supplying them are stimulated by an electrical current. Yet the experiments showed that the will power in general is unabated, for when the subject was unable to bring the exhausted muscles of the second finger into play he could make as strong contractions as ever with the extensor muscles of the thumb or of those of the same finger of the opposite hand. Hence Dr. LOMBARD concludes that the fatigue is located in some of the lower centres, perhaps of the spinal cord. It is remarkable, however, that, even when fatigue is complete, on continuing the efforts to raise the weight periodic returns of power were observed, which were probably of central origin. Speaking broadly, muscular power is greater in the morning than at night, though this is liable to vary under the influence of meteorological conditions, and the fall of the curve of power through the day is checked at regular intervals by the meals. The effect of exercise was very noticeable in increasing the power. Thus it appeared that whilst, when the first observation was taken, it was only possible to raise the two-kilogramme weight thirty times with a total amount of work of 2·92 kilogrammetres, on the twenty-third day no less than 778 contractions were made before exhaustion occurred, with a total amount of work of 36·86 kilogrammetres, the actual strength being thus increased nearly thirteen times, which is very encouraging to those flaccid inhabitants of large towns who endeavour to renovate their debilitated bodily powers by moderate exercise in the open air for a month or so in summer or in autumn. The effect of alterations of atmospheric pressure were carefully examined, with the result that, though no constant relation between the work and the absolute atmospheric pressure was found, it was noticed that the power often increased when the barometer was rising and decreased when it was falling; and, as the research advanced, Dr. LOMBARD became more and more convinced that he was influenced by the changes in the height of the barometer rather than by the absolute atmospheric pressure; so that modifications in the power of his muscles were very observable coinciding with the diurnal alterations in the barometric pressure, and quite independent of the general height of the mercury. There appeared to be two well-marked maxima in the twenty-four hours, the maxima occurring at 10—11 A.M. and P.M. and the minima at 3—4 A.M. and P.M. The influence of tobacco and of alcohol was finally investigated, and with results that are certainly remarkable. These drugs seem to have an antagonistic effect. Tobacco acts rapidly as a depressing agent, and its influence quickly passes away. Alcohol, on the contrary, acts as a stimulating agent, and it increases the endurance of the muscles. In one experiment with tobacco the total work in kilogrammetres at 8.30 A.M. was 10·25, but eighteen minutes after smoking a cigar of medium strength the total work fell to 6 kilogrammetres, and an hour after to little more than 2 kilogrammetres. But at 11.30 A.M it had risen again to 10·25. This is a result well worthy of the attention of all smokers about to engage in any physical contest. The effect of alcohol is not less marked in the opposite direction. The whole of this communication is very suggestive, and is deserving of the careful attention of physiologists and of physicians.

THE profession in the colonies of Great Britain is, on the whole, sound in its determination to be faithful to the great traditions of professional method and conduct. It is, perhaps, not remarkable that in countries so young, with society in a democratic form, and a large admixture of men of an independent and unconventional type, some liberties should be taken with old-established professional modesty and reserve. Some time ago we made allusion to this state of matters in Victoria with regret, but with a sense of duty. A correspondent in Australia forwards us illustrations of the fact that in New South Wales matters are even worse than in Victoria. Not only is the number of avowed quacks much greater, but the practice of advertising by qualified practitioners is deplorably common. He sends us several specimens. "Dr. M. PERRY, M.R.C.S., L.S.A.," advertises himself as a specialist for nervous complaints. His work on nervous diseases is free, and he has medi-

Digitized by Google

cated electrical baths specially adapted for the treatment of nervous complaints. The following are two other advertisements:—"Dr. THOMAS. Examinations passed: M.R.C.S. and L.M. Eng., L.R.C.P. Eng. Dr. THOMAS offers safe and skilful treatment for the cure of nervous, skin, and contagious diseases. Consulting rooms: 244, Castlereagh-street, opposite the Royal Standard Theatre. Hours from 9 A.M. till 8 P.M." "Dr. ALEXANDER PATERSON, A.M., M.D., Specialist Chronic and Nervous Diseases &c." Dr. ALEXANDER M. JOHNSON, however, modestly contents himself with the announcement that he is a legally qualified practitioner. Such advertisements in the chief daily papers of the great cities show a decided laxity in professional ethics. Our correspondent adds further illustrations from his own personal knowledge. He has known a graduate share a case with a quack. In a consultation he has heard the consultant offer further attendance, and in another case attend without offering, until refused admission. He complains that the medical laws and General Council of the colony permit such "flagrant breaches of moral and professional etiquette." We firmly believe that such conduct has the strong reprobation of the bulk of the profession. But the profession must bestir itself to denounce and disown all who practise it. For such persons grow bold by their own defiance of established ethics and construct theories for their own justification. A remarkable instance is forwarded to us in the batch of papers from which the above unseemly and discreditable advertisements are taken. It is in the form of a letter signed by ALEXANDER PATERSON, A.M., M.D., F.R.C.S.—presumably the same graduate who advertises himself as a specialist in chronic and nervous diseases. The occasion of Dr. PATERSON'S letter is the fact of a Bill being before Parliament at present, which has for its object, as our Medical Act has, to enable the public to distinguish between qualified and unqualified practitioners, and which very properly contains a clause giving to the Medical Council of New South Wales power to strike off the Medical Register the name of any practitioner whose name has been erased from any recognised body from which he obtained his qualification. Dr. PATERSON points out that the qualifying body may remove the name of a person for conduct derogatory to the honour and dignity of the profession—"that is, for a matter of etiquette or sentiment, not misconduct." He uses strange words to denounce such action and powers on the part of the qualifying bodies, and asks: "What have the public to do with maintaining the honour and dignity of the profession?" We answer unhesitatingly that the public has everything to do with the honour and dignity of the profession, and that its representatives are highly wise in enacting laws that tend to the maintenance of them. Dr. PATERSON makes two points: First, that so long as a man is "qualified," in the sense of being competent, he has a right to be on the Register. The second is that if a medical man errs in conduct he should be judged by the ordinary courts, and not by a professional tribunal. He should have the same justice as a common culprit. The argument may sound plausible; but it is hollow, and it is discreditable. Every other profession regulates itself and lays down its own standard of honour. The Law and the Church have each its own domestic and internal authority and discipline. It has ever been so in the medical profession. And we see no reason for departing from it. Dr. PATERSON must know that it is the satisfaction of a man to be judged by his peers, and that only professional men can be judges of professional conduct. The public has the greatest possible interest in the maintenance of a high code of professional conduct which represses pretension and vaunting after the manner of quacks. It is only professional men that can be judges of the public evil done by such a system and by other acts and methods of men who hold themselves out as being something superior. The very development of specialism makes the maintenance of the strictest professional methods in practice essential. Otherwise the public will be hopelessly injured. Men like these advertising practitioners want incongruous and inconsistent advantages. They want to be in a profession and have all the honour and respectability that attach to its code of morals and its traditions, and they wish to have all the freedom of quack doctors and nostrum vendors. They may have one or the other of these, but they cannot have both. If they think so little of the judgment of a professional council and value it so lightly they should show more dignity in bearing the natural consequences of such judgment. We are asked in effect, What is mere etiquette or honour compared with qualification? The answer is that from HIPPOCRATES downwards the moral character and the dignified behaviour of medical men have been regarded as an essential part of their "qualification" for the great duties entrusted to them. In the judgment of the public the duties of medical men are so important, and withal so delicate and refined, that it has made the profession the judge of its own members alike in the public and the professional interest. This is found to be for the good of the mother country. It is not likely to be less beneficial in her colonies. Medical authorities have no pleasure in erasing the names of their diplomates, and the public may be assured that when they do so it is for good public and professional reasons.

Annotations.

"Ne quid nimis."

NOTIFICATION OF MEASLES.

THE District Committee of the First or Upper District of the County of Renfrew has determined to add measles to the list of diseases to be notified under the Notification Act. The following is the resolution of the committee: "The District Committee of the First or Upper District of the County of Renfrew, as local authority under the Public Health (Scotland) Act, 1867, within the bounds of the said First or Upper District of the County of Renfrew, hereby order that the Infectious Disease (Notification) Act, 1889, shall apply, in their district, to the following infectious disease—viz., measles; and further order that this resolution shall come into force eight days after this order has been approved of by the Board of Supervision and publication of the advertisement thereof, in terms of the Act of Parliament—that is to say, on the eighth day of February, 1892." Dr. Munro, in forwarding this circular to the medical men of the district, properly invites notifica-

tion at the earliest possible moment. But he adds a sentence which seems to one of our correspondents a little *ultra vires:* "Further, we do not desire to have notification of cases of measles occurring in households within three weeks of the notification of the first case." Our correspondent asks: "Has the medical officer power to say that certain cases of measles shall, and others shall not, be notified?" The question is finely legal. But Dr. Munro is not likely, either for himself or his "authority," to act illegally. The extension of the Act to measles is in the power of the local authority, to which we may accord the right of defining the extension. There is no limitation of cases of measles in the resolution of the authority.

LAST YEAR'S CHOLERA IN ASIATIC TURKEY.

THE real extent of the late prevalence of cholera in Asiatic Turkey may never be known, but certain official returns dealing with the subject have recently been compiled in Constantinople. The outbreak is referred to as having been first noted at Herim, near Aleppo, on June 9th last, and before its cessation in mid-November 1659 persons are stated to have died of the disease in the villayet of Aleppo. In Damascus, between Oct. 18th, 1891, and the beginning of the second week of January last, 801 fatal cases are stated to have occurred. In the Hedjaz, including Mecca, Medina, and sundry other holy places, 3178 persons are reported to have died of cholera in July and August; and following on this, 818 fatal cases occurred in the villayet of Yemen, in the south of Arabia, during the months of October and December. Thus, some 6500 cholera deaths are known to have occurred in the places named. But there still remain the returns for Beyrout, which had not at the time of the report come in; and also those for the country parts of the province of Damascus, as to which it is implied that they may never be forthcoming. Adding the probable deaths in these localities to the list already received, it is estimated that some 10,000 people died of cholera in Asiatic Turkey during the latter half of last year, notwithstanding the fact that the distribution of the population is very sparse, except at certain spots during the pilgrimage period in Arabia.

THE OPIUM CONTROVERSY.

IT is with opium as with alcohol. We are continually hearing from opposite standpoints "the truth" about it. As yet, however, the unpractised hearer, however candid, finds himself so beset with contrary arguments that he has little chance of arriving at an exact opinion on the subject of its use or its abuse. We had occasion recently to notice the significant fact that a memorial condemnatory of the growth and sale of the drug, as now permitted by the Indian Government, had received the signatures of some five thousand British medical practitioners, a considerable number of these having had, we may state, personal observation of the opium habit as practised in China or India. On the other hand, we have a mass of official Indian testimony, largely drawn, moreover, from non-medical sources, which is opposed to the view that the use of opium has gravely prejudiced the health of our fellow-subjects in that country, that it is decidedly increasing, or that its manufacture there has any marked influence on the maintenance of opium-eating and smoking in China. According to this evidence, not only is the drug, if used in moderation, not injurious, but it is in some cases—notably those of persons exposed, as in Assam and Eastern Bengal, to damp and malaria—positively beneficial; it is conservative of physical endurance, it enables the consumer to live healthily on less food than he would otherwise require; it does not, as asserted, cloud his mental faculties, and, even if hurtful, it is so by reason either of adulteration with Indian hemp or of excessive indulgence. They assure us also that the Chinese objection to its importation is only pretence, and intended to protect the privileges of native producers. We observe, however, that even these advocates of its utility do not deny the capacity for mischief possessed by opium if indiscreetly taken. Neither do they dispute its essentially and strongly poisonous character. They show, moreover, no direct or indirect advantage worth naming as arising from its consumption, unless in the presence of illness or as a preventive of malarial infection. These facts, in our opinion, are quite sufficient to justify its restriction to purely therapeutic uses, the more so that it is, if we may trust the teaching of modern observation, by no means the best safeguard against malaria. As regards the attitude of the Chinese Government, we may note a statement by the Viceroy Li Hung Chang in 1881, in which he resents on moral grounds the encouragement given by this country to the opium habit in his own, and declares that the opium war must be taken as China's ineffectual protest against our action. Our ambassadors to China, Sir Rutherford Alcock and Sir Thomas Wade, unlike some critics less favoured as to means of observation, were convinced of the sincerity of these protestations. In Burmah, it is said, matters are coming to a condition no more hopeful than that of her greater neighbours, foreigners and the natives alike indulging freely, and with obvious injury to health and morals, in the same seductive habit. In the face of such facts as these we confess that we can see but one way of escape from the difficulties which surround this question—that is, the legal restriction of opium to its use for purely medical purposes.

EASY CENSURE OF MEDICAL OFFICERS OF WORKHOUSES.

THE *Weekly News and Clerkenwell Chronicle* and other local papers have lately very naturally given some prominence to a motion of the Holborn Guardians censuring the esteemed medical officer of the City-road Workhouse, Dr. Yarrow. We have never known the censure of a medical officer, to say nothing of a medical officer of twenty-one years' faithful and excellent service, to have such an infirm basis. The censure had reference to a man named Reeves, forty-three years old, who had been suffering for months from chronic bronchitis. He was admitted on Dec. 23rd, having walked to the workhouse, and within five minutes of his admission was seen by Dr. Yarrow and ordered to Highgate Infirmary. The workhouse, according to Dr. Yarrow's version and the statement of one of the guardians, is not equipped for the treatment of other than cases of old age and its infirmities, and very inadequately for these. There is only one trained nurse for day duty to about 300 aged sick, and for night work only two untrained nurses. About 1 o'clock P.M. Dr. Yarrow saw the man again, after a dinner of beef-tea and bread. At 3.25 a message was sent to the medical officer that Reeves *had been taken very ill*, and desiring his attendance. Dr. Yarrow came in at 4, and was at the workhouse at 4.15, and prescribed for the patient. He saw him again at 8.20. Reeves was still breathing with difficulty, and on the next day he died, having been seen four or five times by Dr. Yarrow. The two points in the censure were that Dr. Yarrow had not given active treatment to Reeves after ordering him to the infirmary; and that there was an error of judgment in sending him to the infirmary on a foggy day. The short answer to these charges is that a man who had walked to the workhouse was presumably fit to be removed in an ambulance to a more fit and comfortable place, and that it was reasonable under the circumstances to defer active treatment, though a dose of mixture kept in the dispensary had been given. The very language of the master's message shows that a change for

the worse took place after Dr. Yarrow's visit at 1 o'clock. What conceivable justice is there in blaming Dr. Yarrow for this? The least knowledge of such cases in winter months is enough to show that such rapid changes do constantly happen. What are we to think of guardians who on such a basis can found charges against such a man as Dr. Yarrow, who has filled his office for twenty-one years without a charge of neglect? Equally groundless is the attempt, as the *Weekly News and Clerkenwell Chronicle* points out in a very just article, of attempting to found a complaint against Dr. Yarrow for occasional short visits to the workhouse, as on Sundays. Judging from the record of this incident, Dr. Yarrow would seem almost to live in the hospital. Many guardians seem to have a notion that there should be a resident medical officer. There is no evidence that anyone has suffered for want of one, though, according to Dr. Yarrow, there is much need of improvement in the nursing staff. If the guardians really wish to make different medical arrangements, let them discuss them impersonally and do full justice to one who has served them so well. The interests of the poor must not be made a cover for unreasonable treatment of a medical officer. We rejoice that the Local Government Board has been asked to give judgment on these facts. Dr. Yarrow should, and no doubt will, court the fullest investigation. If the interests of the sick poor in workhouses are to be promoted it will not be by disproportionate charges against medical officers, especially in the case of one with a history like that of Dr. Yarrow.

ROYAL MEDICAL BENEVOLENT COLLEGE.

THE biennial festival of this College will be held on Tuesday, April 5th, at the Hôtel Métropole, at 6.30 P.M., when the Right Hon. David Evans, the Lord Mayor, will preside. The sheriffs of London will take part in the proceedings. The council of this important medical charity is desirous of raising funds to meet more fully the annual outlay on the benevolent side of the work, which is very considerable. They have at heart also the raising of a special fund of about £26,000, which would enable them to augment the incomes of the pensioners at present residing at Epsom, and thereby enable them to live amongst their relatives and friends. This proposal appeals directly to the active support of all medical men on the several grounds of sentiment, policy, and economy. By its realisation it will benefit the pensioners as well as the pupils, and in the long run must add to the usefulness of the College. It will afford us great pleasure to be called upon to redeem our promise of £1000, and we sincerely hope that all medical men will make a great effort to help the Council to carry out this beneficent scheme. If this could be done, the Asylum buildings could be set free for an important part of the extensions, which have been rendered necessary by the growth of the school.

FUMES FROM HIGH EXPLOSIVES IN MINES.

THE federated Institution of Mining Engineers have done good service by publishing the results of some important investigations on the effect on the air of coal mines produced by the use of the new explosives, roburite and tonite, in place of gunpowder. The new agents are very powerful, and as explosives they do not appear to be especially dangerous in use. But it was open to grave doubt whether the products yielded by their explosion might not exercise an injurious influence on the health of the workmen. Roburite is a mixture of ammonium nitrate with chloro-dinitro-benzene, the latter compound being expressed by the formula $C_6H_3Cl(NO_2)_2$. The compounds obtained by its explosion are said to be carbonic acid gas, hydrochloric acid, nitrogen, and water, so that complete conversion into gas takes place; but it seemed quite possible that nitrous fumes—and it was almost certain that carbonic oxide—would be formed. Tonite is a mixture of equal weights of gun-cotton and barium nitrate, and its decomposition on explosion results mainly in the formation of barium carbonate, carbonic acid gas, water, nitrogen, and oxygen; but here again there seemed a risk that poisonous vapours might be emitted. An experimental investigation was therefore undertaken by the Durham Coal-owners' Association and the Durham Miners' Association, the chemical portion of the examination being allotted to Professor Bedson of Durham, the medical study to Dr. Drummond and Dr. Hume, and the engineering management to Mr. Walter Brown. The results are now published in the form of a pamphlet. Blasting operations were carried on at intervals from 1889 to 1891, and by skilfully devised apparatus Professor Bedson succeeded in collecting and analysing samples of the gases almost immediately after the shots were fired, not only at some little distance from the spot, but also from the immediate neighbourhood. Comparative experiments with gunpowder were made, and the general conclusion reached was that the fumes emitted from the new explosives were less rather than more dangerous than those from gunpowder. Carbonic oxide was found in every case, but only in minute quantity. Hydrochloric acid does not appear to have been detected at all, which is curious, as it is certainly formed during the combustion of roburite. We infer that the whole of the barium is retained in the solid state as carbonate, for no allusion is made to its presence in the fumes. Of course barium carbonate is a very fixed substance; but, considering the enormous temperature caused by the explosion, it might have been feared that some traces of this very poisonous metal would linger in the vapours for a short time, possibly in suspension.

AMŒBIC DYSENTERY.

FOR some time past Drs. Councilman and Lafleur have been investigating a large number of cases of dysentery, caused, as they believe, by the amœba coli, or, as they prefer to call it, the "amœba dysenteriæ" A summary of their work is given in the *Boston Medical and Surgical Journal* of Dec. 24th, 1891. They maintain that amœbic dysentery is a distinct disease caused by amœbæ which enter the body and produce characteristic lesions of the intestine. They may also produce abscesses of the liver with or without lesions of the lung. Such abscesses differ in their characteristics from those occurring in other forms of dysentery. Dr. Lafleur is responsible for the clinical part of the work. He found the onset of this disease to be variable, its course irregular, with frequent exacerbations and intermissions, but tending towards chronicity. Tenesmus was infrequent; the stools contained mucus mixed with blood, but differed in general characters from those seen in other kinds of dysentery. In chronic cases, with a fairly good appetite and digestion, a grave anæmia might exist, without the escape of blood from the rectum. The prognosis is always uncertain; death may take place at any period in the course of the disease, and recovery, when it takes place, is gradual. The essential feature in the diagnosis is the detection of actively moving amœbæ in the stools, sputum, or aspirated contents of a hepatic abscess. Dr. Councilman concludes that the amœbæ in food or drink reach the large intestine, where they find favourable conditions for their development. They multiply rapidly, and cause a superficial necrosis and an increased flow of mucus. They penetrate the mucous membrane passing between the glands and invade the submucous

Digitized by Google

tissue, where they give rise to an œdematous swelling. The overlying tissue, being thus deprived of its blood-supply, dies, and ulceration is the result. The ulcers increase by a progressive, undermining process, though their typical course and appearance may be modified by the action of associated bacteria. In some cases the amœbæ pass into the muscular coat, producing changes similar to those seen in the submucous layer. These lesions thus correspond with those generally described under the term "follicular dysentery" rather than with those included under the catarrhal and diphtheritic varieties. Dr. Councilman thinks the amœbæ usually invade the liver by crossing the peritoneal cavity, although they may be found in lymphatics and bloodvessels. He bases this view upon the absence of amœbæ in the lymph glands and the usual limitation of the abscess to the upper or lower surface of the right lobe of the liver, whereas abscesses from portal embolism should be found in either lobe, deep-seated as well as superficial. The abscess in the lung is usually found in one particular place—namely, the lower lobe of the right lung, where it is in contact with the diaphragm. It frequently arises from the direct extension of the hepatic abscess through the diaphragm, although this muscle may sometimes be intact. The typical effect of the amœbæ is best seen in the liver, where they appear to produce a necrosis of the tissue, and a solution of the inter-cellular substance. The so-called abscess is thus made up of detritus, and not of pus corpuscles.

DEVELOPMENT OF HEALTH RESORTS IN SIBERIA.

SIBERIA is not a place where, according to the conceptions of its climate and topography prevalent in this country, health resorts of an agreeable character are to be looked for. The inhabitants, however, seem determined to establish "baths" on the type of those met with on the Continent; and an energetic merchant, M. Kukhterin, has already supplied the means for the scientific examination of Lake Ingol in the Yeniseiski government, some 200 miles to the east of Tomsk. This examination was entrusted to Dr. Stanilaus Zaleski, Professor of Chemistry in the University of Tomsk. His report, which is embodied in an illustrated pamphlet, shows that, though the waters of the lake are of the chemically indifferent variety, they, as well as the mud, are suitable for the treatment of a good many classes of chronic affections. It is proposed to build a regular hydropathic establishment on the shore. The surrounding country is very sparsely populated, but the waters have been used, in an empirical manner of course, with, it is said, considerable success. The Russian Government appears to be anxious to develop the hydro-therapeutical resources of Siberia, for Professor Zaleski has received instructions to continue his investigations. The next locality upon which he is to report is Lake Shiro, in the Yeniseiski government. It would seem that the Tomsk University, though only established about four years, has already proved itself an important centre of scientific investigation. It is as yet, however, very poor and insufficiently equipped. Still, with a staff of enthusiastic young professors, such as it evidently has, it seems not unlikely to accomplish much for the enlightenment of a somewhat dark region of the world.

HEALTH AND GODLINESS

IN an age wherein the duties of a brother's keeper are probably more fully admitted than in any preceding epoch it will be allowed that the purposes of the society known as the White Cross League are wholly worthy of support and imitation. They may be briefly summarised as tending to promote among all classes the growth of a spirit and practice of purity. This is to be attained by the operation of two agencies, which, however, are clearly and rightly recognised by the members of the League as double rather than separate, so closely are they and the circumstances with which they deal associated. We have in the first place that which is moral and personal, and which inculcates directly the necessity of individual temperance and chastity, and we have also that which, by amending unsuitable conditions due to neglect, aims at producing a soil and environment which will encourage the growth of virtue. It is in this latter project that we are especially interested. The Rev. J. W. Horsley, in a paper lately published by the League, directs attention to the close connexion already known to exist between personal immorality and insanitary home surroundings. His experience of parish work, he tells us, has abundantly proved not only this fact, but no less clearly the power of reclamation which has been committed as a public trust of legislation to any and all householders willing to apply it. He expresses in a style as luminous as it is concise the practical drift of those Acts which make for the promotion of domestic cleanliness and decent living, from the old Nuisance Removal Act of 1855 to the Public Health Act for London which came into force last January. Into the provisions of these it is not needful that we should now enter, but we would again state our appreciation of the practical wisdom, at once worldly and other-worldly, which has guided the League and the author of this paper in striking thus deeply at some of the main roots of national illness and ill-doing. The White Cross League is a Church organisation. We have said enough to show that its work is universal and humane—the common sphere therefore of every ethical, moral, and religious force.

DEATH OF DR. JAMES ROSS.

WE regret to have to announce the death of Professor James Ross, lecturer on Medicine in Owens College, Manchester. He was a graduate of Aberdeen, and came to Manchester as pathologist to the Royal Infirmary of that city, directing himself particularly to researches on nerves. An outcome of his investigations on that subject was his "Treatise on the Diseases of the Nervous System," published in 1833. He also published a "Handbook of Diseases of the Nervous System." He wrote many papers, among the more noteworthy of which were "The Segmental Distribution of Sensory Disorders," a paper on "Evolution," and one on "Memory." He was an acute and philosophic observer of disease. As a psychologist and a scientific physician he occupied the first rank. A fuller notice is reserved for publication in our next issue.

THE CHEEKS IN GLASS-BLOWERS.

IN the last number of the *Progrès Médical* Dr. Regnault describes the condition of dilatation of the cheeks which occurs in glass-blowers, and which, so far as he has discovered, has not received much attention as regards the condition actually present and the cause of it. The work of glass-blowing is one requiring considerable skill and delicacy, and the apprenticeship necessary is a long one. Consequently boys commence the work, as a rule, at some time between the ages of twelve and fifteen, when the cheeks are not yet formed. The change is a gradual one, and for the most part takes place imperceptibly. When it is commencing there may be slight and unimportant pain. The pain disappears when the dilatation is achieved. It varies in degree, and frequently is only perceived when the cheeks are inflated. The limits of the swelling are inferiorly a line joining the chin and the ear, following the inferior oblique line of the lower maxilla; superiorly, another line starting from the ala of the nose, running up to the malar bone to strike the anterior limit of the masseter, which forms the posterior

Digitized by Google

boundary of the swelling. The dilated wall is thus formed of the aponeurosis of the cheek, and of muscles such as the levator alæ nasi, the zygomatics, the orbicularis oris, and especially the buccinator. It is rare for this condition to be so marked as to be noticeable during repose. An interesting accompaniment is the dilatation of Stenson's duct. After the patient has ceased to blow and the cheeks have subsided there remains still some air in the canal, and gaseous crepitation can be perceived on pressing over it. Examination of the mucous membrane also shows the orifice of the canal considerably dilated, and a plug three millimetres in diameter can be inserted into it. Fortunately, the inconveniences to which the condition gives rise are for the most part slight, consisting of occasionally some slight difficulty in keeping the food from getting between the teeth and the cheek, and a tendency to white furring of the inside of the cheek, necessitating the occasional use of an antiseptic mouth-wash. Dr. Regnault gives the particulars of three cases which he has observed clinically, and calls attention to the interesting fact that sculptors, in representing Tritons blowing into shells, have reproduced exactly the deformity described.

FILARIASIS.

AMONG twenty-six officers and colonial officials admitted to the Val-de-Grâce Hospital between May 1st, 1890, and Feb. 1st, 1891, Professor Moty observed four cases of the above disease, and two other cases in the parents or friends of the patients. Four, however, of those admitted to the hospital had been abroad for so short a time that they may be left out of the calculation, leaving six cases among twenty-two persons who had spent a considerable time in the colonies. In spite of its frequency, this disease does not appear to be generally recognised abroad, as in none of the above cases had it been diagnosed. It was only upon undertaking an operation for the radical cure of a supposed hernia that the tumour was found to consist of dilated lymphatics. Professor Moty came to the following conclusions: That filariasis is an aseptic parasitic disease due to the presence of the filaria sanguinis hominis; that it is of frequent occurrence in the French colonies, and has been recently met with in New Caledonia. It most often appears as an enlargement of the glands and lymphatics of the groin and spermatic cord, due to the irritation of the filaria and its embryos. It can be recognised by such symptoms as chyluria, hæmaturia, &c.; but the diagnosis in each case should be confirmed by the detection of the embryos in the blood. Neither internal nor palliative treatment is of the slightest use. Excision or amputation is necessary in severe cases, and is attended with the happiest results, the removal of the hypertrophied tissue causing the adult filaria to disappear.

LIFE ASSURANCE AND THE MEDICAL PROFESSION.

WE find that THE LANCET is credited in quarters that should be better informed with having advocated a form of life assurance for medical men in which the premiums increase as the policy grows older. This is an entire misapprehension. What we have recommended is a form of long-term temporary assurance under which the premium would be considerably less than for a whole-term policy, but uniform while the policy continued in existence. There has been a great outgrowth within the past few months of life assurance schemes, under which the premiums vary from year to year, being calculated to do no more than meet in every year the current risk. To a policy in this form we have no root-and-branch objection if both parties to it clearly understand what the position is. But to the mode of advertisement which is adopted by votaries of the new system we see the strongest possible objection. Prospectuses have been brought recently to our notice in which tables constructed on this plan are given, and shown in comparison with other tables stated to represent the term of the ordinary assurance companies, in which are entered the premiums chargeable not only to cover the current risk, but also to purchase a right of *renewal at the same rate* during the whole continuance of the assurance. As *this right of renewal* forms no part of the contract which the issuers of the prospectuses in question offer to their customers, the comparison of which we speak is certainly very misleading, and indeed entirely without point except upon the wholly false assumption that what is offered by the one company is an equivalent of what is offered by the other. We trust that our contemporaries, when they do us the honour to quote our opinions, will be at the pains to quote them correctly, and, in particular, will not use general terms, which may seem, even though remotely, to connect us with schemes which, if we felt compelled to refer to them at all, we should notice only in terms of condemnation.

RESEARCHES ON THE BLOOD IN DISEASE.

THANKS to the more exact methods of estimating the number of corpuscles in the blood and their richness in hæmoglobin, we are becoming possessed of a large amount of information respecting the variations presented by these elements in physiological and pathological conditions. The most recent contribution to the subject is by Dr. Carl Sadler, whose researches were pursued in the clinic of Prof. von Jaksch at Prague, and the details of which form a supplement to the *Fortschritte der Medicin* (vol. x., No. 4). The monograph contains the results of very numerous observations (made with the Thoma-Zeiss hæmacytometer and the hæmometer of von Fleischl) in cases of diseases of the blood, pneumonia, pleurisy, pericarditis, peritonitis, acute rheumatism, meningitis, scarlet fever, malaria, typhoid fever, peri-typhlitis, Weil's disease, puerperal "sepsis," tuberculosis, bronchitis, nephritis, morbus cordis, gastric catarrh and dilatation, carcinoma (of stomach mainly), sarcoma, lymphadenitis, syphilis, cerebral tumour, cirrhosis of liver, and cholera nostras—a lengthy list, covering a wide range of disease. The results are drawn up on a methodical plan, and are well worthy of study in each individual instance; but it must suffice here to cite the chief facts contained in the summary that closes the monograph. In acute diseases Dr. Sadler finds that there is constantly a decrease of red blood-corpuscles, but mostly not very marked. In chronic diseases the diminution is greater, especially in such as exhibit cachexia, and there is a proportionate diminution in the amount of hæmoglobin. An exception to this is met with in tuberculosis so long as nutrition is fairly well preserved. Nor does valvular disease of the heart, particularly mitral disease, affect the number of corpuscles. In chlorosis the corpuscles may long remain at the normal standard, whilst the hæmoglobin markedly falls, a confirmation of a well-established fact. In other cases of anæmia, the essential form and those due to losses of blood, atrophy of stomach, and other causes, the decline in corpuscular richness takes place *pari passu* with that of the hæmoglobin. Acute and profuse diarrhœa produces a notable increase in the proportion of corpuscles and hæmoglobin, attributable to inspissation of the blood, and this may account for the apparent maintenance of a fairly normal standard in some cases of typhoid fever. Dr. Sadler found a diminution in the number of white blood-corpuscles in malaria, apart from the administration of quinine. Leucocytosis is proved to occur during digestion, and also during the puerperal period and the first days of lactation. Pathological leucocytosis is found in all diseases

Digitized by Google

accompanied by exudation, such as pneumonia and serous inflammation, including acute rheumatism, but not invariably. An explanation of the variation may perhaps be found in the different kinds of exudation that occur; whilst the leucocytosis itself has been explained by the absorption of "nuclein" set free from the disintegration of the exudate. Leucocytosis does not occur in uncomplicated typhoid fever, or in tuberculosis (except during the reaction produced by injections of tuberculin). It was present in only one-half of the cases of carcinoma examined, and had relation rather to the supervention of ulceration than to infection of lymphatic glands. Singularly, in contrast to carcinoma, leucocytosis is invariably present in cases of sarcoma, the reason for which is not at present obvious. Dr. Sadler did not find any increase of white corpuscles in cases of tubercular lymphadenitis which had not proceeded to suppuration.

THE FEEBLE-MINDED.

THERE is a widespread class of people from whom personal sympathy is seldom withheld, but to whom, from restrictions in one way or another, the tangible charity of boards of guardians and other authorities cannot be extended. This is the class of persons who, in the technical sense of the term, are "feeble-minded." Investigations made on children in Board schools, the results of which are to form the subject of the Milroy lectures to be delivered in the course of this month at the Royal College of Physicians, and abstracts of which will appear in the columns of THE LANCET, have shown that the number of children comprised in this group is much larger than was formerly supposed. But no powers exist whereby boards of guardians can place them in suitable institutions. A deputation introduced by Dr. Farquharson waited upon Mr. Ritchie on Feb. 29th to point this out to him, and to ask his assistance on behalf of these poor creatures, who are from natural defects unable to maintain themselves by honest labour. Mr. Ritchie is always sympathetic in such cases, and the deputation was assured that their requisition was one of "no complication," but simply implied a small extension of the powers already existing with regard to the deaf, dumb, and blind. Personally, Mr. Ritchie has a strong leaning in the direction of rendering whatever assistance he legitimately can to the object which the deputation had in view, and their proposals will no doubt be very carefully considered. Of course there are questions which require thought; for instance, whether it is the best thing for the feeble-minded to be grouped together without association with others of strong minds, and, if not, the proposal of some alternative plan. No doubt these and similar points will be judiciously considered by Mr. Ritchie and his advisers, and we feel assured that in any event the objects of the deputation will be to a large extent realised.

PTOMAINES IN THE URINE OF A PATIENT SUFFERING FROM EXOPHTHALMIC GOITRE.

DRS. E. BOINET AND SILBERT have obtained from the urine of a woman suffering from exophthalmic goitre, complicated with paralysis of the right arm and irregular action of the heart, several ptomaines which have produced in animals symptoms similar to those from which the patient suffered. The residue of the urine after evaporation injected in minute quantities into the vein of a rabbit's ear caused convulsions and death. In the frog it caused gradual slowing of the heart's action, followed by arrest in diastole accompanied by convulsions. By a modification of Gautier's method they have obtained from the urine, concentrated by boiling, two series of ptomaines—viz., ptomaines *A* by treatment with caustic soda, ptomaines *B* by treatment with oxalic acid. Each of the ptomaines, called after the agent by which it has been isolated, as amylic alcohol, benzine, or ether, is possessed of different properties, as shown by experiments upon rabbits, guinea-pigs, and frogs. The ptomaine *A* obtained by alcohol causes convulsions with slowing and feebleness of the heart's action, ending in arrest in diastole. The ptomaine *A* obtained by benzine causes more powerful convulsive movements, but its action on the heart is less marked. The ptomaine *A* obtained by ether caused at first increased muscular excitability, and, unlike the others in the *A* series, arrest of the heart in systole. The ptomaine *B* obtained by alcohol causes motor paralysis with a fall of temperature, a slight transitory increase in the force of the heart's contractions, followed by feebleness, loss of rhythm, and arrest in diastole. The ptomaine *B* obtained by ether causes slight convulsive movements and arrest of the heart in systole.

SMALL-POX WARNINGS.

SMALL-POX is making insidious advances in a number of places, and at this season of the year the occurrence is one about which it behoves all sanitary authorities to be watchful. The disease has gained access to our shores in several of our port districts; and, whether from this cause or owing to infection from which we are rarely ourselves entirely free, the disease has manifested itself in some important centres of inland population. One of the latest warnings comes from St. Pancras, where, according to Dr. Sykes, seven cases of small-pox have occurred amongst waiters in hotels who have recently arrived from Switzerland, a country where the disease has for some time past been prevalent. Amongst the towns that have been the seats of small-pox on varying scales during recent months are Batley, Dewsbury, Leeds, Liverpool, Southampton and its vicinity, Great Yarmouth, Oldham, Nottingham, Huddersfield, and Cardiff, isolated cases alone having occurred in the two latter. At Dewsbury and Liverpool the disease continues without abatement.

SO-CALLED "SPONTANEOUS COMBUSTION."

UNDER this title Dr. Hartwell records a curious experience which he had recently. He was one day hastily summoned into the woods while visiting a case in the outskirts of the town in Massachusetts, where he lives, the messenger announcing that her mother was burned alive. On reaching the place indicated a human body was found in an actual state of conflagration. The body was face downwards and resting on the forearms, the upper part of chest, and the left knee. The rest of it was raised and held from the ground by the rigidity of the muscles of the parts. It was burning at the shoulder, on both sides of the abdomen, and on both legs. As Dr. Hartwell reached the spot the bones of the right leg broke with an audible snap, allowing the foot to hang by the muscles and tendons. The right shoulder-joint was exposed, and the intestines protruded through the burnt abdomen. The unburned clothing consisted of parts of a calico dress, a cotton vest, woollen skirt, and thick red woollen under-garment. Apparently the woman—for it was a woman forty-nine years of age, active in her habits and strictly temperate—had been burning stumps, and her clothing had become ignited. Dr. Hartwell's view is that the flesh—in a condition of unusual combustibility—had then caught fire, and had been able of itself to support combustion, and this is all that he means by so-called spontaneous combustion—viz., an undue liability of the flesh to actually burn. His view as to this condition is that it depends upon the fact that human bodies occasionally do possess this increased combustibility by reason of an unusual deposition of fat, and that age and spirit-drinking are factors in that they aid in the accumulation of

Digitized by Google

fat. The interest of the case which he records he claims to lie in the fact that it occurred in a person of middle life, by no means obese, and not addicted to alcoholic indulgence.

PARALYSIS FOLLOWING MEASLES.

DR. JAMES STRATTON CARPENTER records in the *Medical News* of Philadelphia this rather unusual condition. The patient was a female child of three who had a mild attack of measles. On the third day of the illness the mother noticed that she was breathing heavily, and could not be roused. When seen by Dr. Carpenter she was found to be feverish, breathing stertorously, and only able to be roused with difficulty from the stupor, into which she immediately relapsed. She was placed in a lukewarm bran bath, and the rest of the treatment consisted in the administration of what are described as "appropriate remedies." In a few days she was convalescent, but the first attempts at walking revealed weakness and dragging of the right leg. The right arm was also affected, but this had escaped notice, as the child was left-handed. There was no disturbance of what speech is present at that early age, and this was to be expected. During convalescence strychnia was administered in gradually increasing doses, and recovery was complete.

THE SENSE OF EQUILIBRIUM.

OUR Vienna correspondent writes as follows:—At a recent meeting of the Vienna Society of Physicians, Dr. Kreidl, Professor Exner's assistant, reported on the experiments he had made on deaf-mutes concerning the physiology of the labyrinth. Touching the experiments made on this subject by Flourens, Goltz, Mach, and Breuer, he pointed out that the membranous canals of the internal ear should be regarded as the peripheral part of the mechanism of the sense of equilibrium, the sensations of the disturbance of which he takes to be produced by the flow of the fluid in the ampulla and in the membranous canals. If the views of physiologists on the function of the otoliths and the membranous canals be true, it would have been expected that anomalies of the sense of equilibrium should be found in deaf-mutes. Purkinje had previously observed that if a person is made to rotate on his own axis the eyeballs were moved to the side as in nystagmus. This in Dr. Kreidl's experiments was not observed in deaf-mutes to any very large extent. Dr. Kreidl from other experiments is led to regard the otolithic organs as a statical sense.

THE LARYNGOSCOPE IN ENGLAND.

THE recent removal by death of one of the foremost laryngoscopists has revived memories of the early history of the laryngoscope and of its introduction into this country. The rival claims to priority in the actual invention of the instrument, which arose out of the endeavour to apply Garcia's discovery to clinical use, as between Türck of Vienna and Czermak of Pesth, need not be reopened. They were decided in the latter's favour by the perfection to which he brought the instrument, the use of which he himself demonstrated in London in 1859. This was the year in which Mackenzie visited Pesth, and became impressed with the value of the new invention as related in our notice of his life (p. 394). At the same time the credit of demonstrating the use of the laryngoscope in London, and of being early in the field in its published description, rests largely with the late Duncan Gibb and Prosser James; for in 1860 the first-named published his treatise on Diseases of the Throat, in which he recommended a steel mirror to inspect the epiglottis; and he subsequently translated some of Czermak's papers for the new Sydenham Society. Dr. Prosser James, also in 1860, gave laryngoscopical demonstrations at the City and Metropolitan Dispensaries, and published the first edition of his work on "Sore-throat," in which he embodied an account of the use of the laryngoscope, and its value in diagnosis and treatment. Although, then, it may be strictly correct to say that Morell Mackenzie first introduced it into this country, yet his published writings on the subject were some years subsequent to those of the two physicians, who, like him, ought to be remembered for their recognition of the importance of Czermak's invention and its utilisation in practice.

VACCINATION.

AN inquest was held last week on the body of an infant who had died shortly after vaccination. The child had been vaccinated in the workhouse of the Wandsworth and Clapham Union twelve days after its birth. Three days after the operation the mother and child left the workhouse, and later the child's arm, it was said, was "highly inflamed." The medical superintendent of the workhouse was consulted and he recommended poultices, but the child died about a week afterwards. Dr. E. T. Smith, who had made a post-mortem examination, gave evidence to the effect that the child had died from congestion of the lungs and exhaustion, due to erysipelas following vaccination. The child had been taken from the workhouse when it was snowing, with only a thin shawl over it. It was stated that the erysipelas was set up by a chill, and that the vaccination had been properly performed. The so-called vaccination censuses have been taken under the auspices of the Society for the Abolition of Compulsory Vaccination in the parish of St. Paul's, Bristol, and at Gainsborough. In the former place the figures published are: total votes recorded 1380; in favour of vaccination, 352; against vaccination, 978; in favour of compulsion, 186; against compulsion, 1193. In Gainsborough the figures given are 2002 votes against compulsory vaccination, and 181 for it. We are not prepared to attach any value to these figures, but if they should really betoken any desire to abolish vaccination in these communities, we can only lament the troubles which will eventually result. English people are, however, credited with being possessed of considerable common sense, and it may be expected that eventually they will understand the necessity of vaccination for the prevention of small-pox, and that opposition to vaccination will to a large extent die out, but perhaps only after disaster has attended its neglect.

THE DEBATE ON PHAGOCYTOSIS.

THE discussion at the Pathological Society upon the doctrine of phagocytosis in relation to immunity seems to gain in interest and definiteness as it proceeds. The issues are becoming more clearly defined as the arguments for and against the doctrine are evolved. Dr. Bristowe, who spoke first at the meeting last Tuesday, did good service in recalling to the minds of his hearers the accepted facts of clinical observation respecting the infective diseases and the question of protection. He showed how difficult it was to explain the latter on any hypothesis yet advanced. Dr. W. Hunter did his best to reconcile the opposing views of the "phagocytists" and the "humoralists," thus adopting a term which reminds one of the controversies of a bygone pathology, and suggesting that after all the root problems of disease remain much the same now as then. Dr. Hunter maintained that the physiological relationship between the cells and the plasma was such as to support the phagocyte position, which had the further merit (not possessed by "humoralism") of novelty. His illustrations of experiments bearing on chemiotaxis, positive and negative, were criticised by Dr. Martin, who showed that they were inconclusive, owing to the inflammation set up by the sponge in-

Digitized by Google

troduced beneath the skin. Moreover, Dr. Martin, who was the chief speaker against phagocytosis that evening, adduced weighty reasons for believing that the changes to which immunity is owing take place in the blood and not in the solid tissues. On the other hand, Dr. Wright, whose lucid speech was an admirable contribution to the debate, candidly admitted that he had recently come round to the opinion that the bactericidal power of tissue-fibrinogen (with which he allied Hankin's "alexine") may best be explained by its acting as a cell stimulant. Mr. Adami and Mr. Bokenham also adduced facts tending rather to support the doctrine of immunity by phagocytosis; and altogether it may be said that many of the arguments advanced at the previous meeting were met by the "phagocytists," whose chief exponent, Dr. Ruffer, will open the adjourned discussion at the next meeting of the Society.

EXECUTION BY ELECTRICITY.

WE are specially pleased to see that the State authorities in New York are about to reconsider the question of capital punishment by electricity, with a view to the abolition of that form of legalised taking of life. It was, indeed, high time for reconsideration. Since we last wrote on this subject another "electrocution" scene has occurred, with results even more revolting than any we have previously recorded. Our contemporary, the New York *Medical Record*, has joined its voice with our own in condemning this so called scientific executioner's work, and has cried "a halt in the revolting experimentation enacted at every execution." All the victims have been killed, it is true, adds our contemporary, "but how?" "In every case repeated strokes were necessary, with torturing intervals for discussion and disputation among the scientific experts; the grim tussle with death timed by stop-watches, while the victim was writhing between scorching electrodes. The details of this dreadful business transcend in cool brutality anything that can be imagined, and yet we are assured that this is the new and approved way of doing a victim to death." These are strong terms, but under the circumstances not one word too strong or too condemnatory. They surely will prevent any further medical participation in these unwholesome deeds. In this country, if medical art were degraded to such participation, the act would not only cause universal indignation against the offenders, but would force the profession at large to raise its powerful and humane voice in repudiation of any and every man in its ranks who dared to take a part in so grave an offence against the national conscience and professional honour.

DEBT RECOVERY AND WATER-SUPPPLY.

A CASE was decided last Saturday at the Westminster Police-court which clearly shows the great inconvenience and injury which threaten the ratepayer who may from any mischance be unable to discharge his account with a London water company. The defendant, who seems to have been overcharged, refused to pay for water which he had not used. The company, not seeing the matter in this light, proceeded to enforce payment by cutting off his household supply, and for seven days—that is, until the hearing of the case in court—persisted in this course. Their attitude in the matter, though entirely legal, was severely criticised by the presiding magistrate, who regretted that none of the various Acts as at present constituted allowed consumers any guarantee against such a high-handed mode of procedure. He was strongly of opinion that the water-supply to any house should under no circumstances be terminable at the will of a company. Debt recovery should rather be arranged, as in the case of parish rates, by taking proceedings in a court of summary jurisdiction. In this opinion we concur. Whatever may be said of the commercial principle involved, it is indeed astonishing that no legal check should be placed upon the application of a process which prohibits the use of an absolute necessity of life and health. Water certainly can under no circumstances be dispensed with, and it is no mitigation to say that the sufferer by an adverse verdict may borrow sufficient for his temporary needs. It is not clear to our mind how he can even do this. Yet his necessities, his health and cleanliness, are intimately connected with the well being of his neighbours, and the case is one in which, if he suffer, others suffer by and with him. Some amendment of the existing law such as that above suggested is therefore evidently needful as a mere matter of sanitary requirement.

THE EXAMINATION OF THE EYES OF SCHOOL CHILDREN.

DR. SYDNEY STEPHENSON has just completed and forwarded to the managers of the Edmonton School Board a report on the state of the eyes in the children of the Croyland-road school, Brettenham road school, and Garfield-road school, the last-named being at New Southgate, a short distance from London. The total number of children examined was 2873, of whom Dr. Stephenson informs us 1214 were boys, 885 girls, and 774 infants. Dr. Stephenson found that forty-seven children were suffering discharge from the eyes, the largest percentage, 2·95, being in the children attending the school at New Southgate, and he very properly points out to the governors that the presence of such discharge is a possible, or he might have said a highly probable, source of danger to other scholars, being capable, if passed from child to child, of giving rise to serious attacks of ophthalmia. He recommends accordingly that the board of management should give the teachers power to refuse admission into the schools of any child who was seen to have discharge from the eyes. Dr. Stephenson examined the defects in the refraction of the eyes in the children, the far larger proportion of which occurred in the Croyland-road school. He dwells strongly on the importance of good eyesight as the chief means of education, "many a case of so-called stupidity meaning nothing more than defective sight." He recommends that the name of any scholar who is observed by the teacher to see imperfectly should be reported, and proper measures taken to procure appropriate spectacles for him, whilst periodic testing of the acuteness of vision should be undertaken. Out of the total number of children there were seventeen who had strabismus.

NEURITIS IN DIABETES.

IN the last number of the *Neurologisches Centralblatt* there is an abstract of a contribution by Eichhorst to the subject of the loss of the patellar reflex in diabetes mellitus. It is based upon the observation of two cases during life, and an examination of the nervous system after death. The first patient was a female, forty-five years of age, who had loss of knee-jerks, slight girdle feeling, no Romberg's symptom, and no ataxy. The urine contained a considerable quantity of sugar. The necropsy revealed atrophy of the pancreas and an unusually large size of the nuclei of the liver cells, but the central nervous system showed no change. In the crural nerves, however, and in the vagi there was a condition of well-marked parenchymatous neuritis. The sciatic nerves were more slightly affected, while the median nerves were normal. Similarly, in the second case, there was a widespread parenchymatous neuritis affecting the crural nerves and also the sciatics, while the median nerves were normal, and the central nervous system showed no change. The absence of the knee-jerk in diabetes, it is further said, is to be ascribed in some cases to a functional disturbance; in

Digitized by Google

others, as the above, to a change in the anterior crural nerve; and the curious statement is made that if the knee-jerk disappears and returns in the course of the illness, the cause is to be regarded as a functional disturbance. No one will deny that in such a case, granted the reliability of the observation, there is a disturbance of the function of the anterior crural nerve present. But so there is in the cases in which there is inflammation of the nerve, and it seems to us unwarrantable to assume that, because the normal condition becomes re-established, there may not have been a structural change in the nerve underlying the evidences which it presented of disordered function.

SCARLET FEVER AT CARDIFF.

A GREAT deal of difficulty is being experienced at Cardiff owing to the failure of the sanitary authority to isolate cases of scarlet fever occurring under circumstances which demand isolation in the interests of the public health. In one instance a prosecution is threatened in connexion with this state of unpreparedness. One thing, however, is evident, and that is that such a town as Cardiff has no right to remain unprepared in such a matter. Some inhabitants advocate the immediate erection of a temporary hospital. It is so rarely that a temporary hospital is found to answer the immediate purposes for which it was erected, that we cannot but urge caution in this respect. What is wanted is a good permanent establishment, capable, if need be, of temporary extension to meet emergencies.

INFLAMMABLE BUTTONS.

INSTANCES are not wanting, unhappily, of the perils arising from the use of easily inflammable material on articles of clothing; but the danger to which Professor C. Vernon Boys has recently called attention is certainly a new as well as an alarming one. It appears that a lady who was standing near a bright but not blazing fire suddenly found herself enveloped in smoke, and a gentleman who came to her rescue succeeded in crushing the ignited portion of her dress, not, however, without severely burning his hand. On investigation the fire was found to have originated from a spot where a large fancy button had been but had disappeared. Similar buttons were subsequently examined, and the results plainly went to show the danger of this style of ornament. The buttons appear to be composed of gun-cotton and camphor, a combination which is not only inflammable, but on the least provocation spontaneously so. It just happens that this unpleasant incident was not followed by any serious results, but that the consequences might have been of a disastrous character is patent to everyone. Experiments of a rough though practical kind made by Professor Boys proved to demonstration that buttons composed of such material were very susceptible to the heat of an ordinary fire, even outside the fender, and at a distance at which the skirts of a dress might any day be found. It is well known that "celluloid" has of recent years been largely substituted for the true material in the manufacture of ivory, tortoiseshell combs, hair-pins, and amber mouthpieces. Some little time ago we heard of a light being accidentally applied to what was presumably the amber mouthpiece of a tobacco pipe. The spurious amber rapidly and instantly ignited, and gave off abundant fumes smelling overpoweringly of camphor. One kind of celluloid is made, we believe, by dissolving 50 parts of gun-cotton in a mixture of 100 parts of ether and 25 of camphor, and evaporating the solvent from the resulting transparent jelly-like mass until it is plastic. It is then exposed in thin plates to the air until it is hard and capable of taking a polish. Billiard balls &c. are prepared by rolling several plates together and rasping the newly formed plate into a coarse powder. Pared potatoes, it is said, also yield a celluloid when similarly treated. The public are advised by Professor Boys to guard themselves from what is likely enough to be a grave source of harm, even to the extent of fatal issues, by taking the precaution of submitting to a very simple test not only buttons that resemble tortoiseshell, but hair pins, combs, and other ornaments, and even toys. On briskly rubbing the button on cloth, a strong smell of camphor is evolved. If this ready test fails, a small portion may be ignited; it will burn energetically with a flaring noise, and the fumes of camphor given off cannot be mistaken. If the article is composed of other material, the smell will probably bring to remembrance that produced on burning feathers. It seems to us that manufacturers have not the least justification for putting such dangerous articles on the market, particularly as we have reason for believing that by incorporating with the celluloid or similar substance made from nitro-cellulose (the product of treating cotton wool with strong nitric acid) a quantity of a metallic salt, such as chloride of tin dissolved in alcohol, ether, or other convenient solvent, the celluloid may be made non-inflammable and perfectly safe.

THE SECRETION OF BILE IN URÆMIA.

IN order to elucidate the character of the secretion of bile in artificially induced uræmia, Dr. Lokianoff of Warsaw tied the ureters close to the bladder in twelve guinea-pigs, collecting the bile of six of these during the first day and of the remaining six during the second day of uræmia. He found, amongst other results, that uræmia tends to reduce the body temperature; as a rule, the liver increases in weight to a slight extent, the blood and the kidneys become richer and the liver and brain poorer in watery constituents, and the secretion of bile is rather less than normal. The production of hepatic tissue is diminished, especially as the uræmia progresses. The bile secreted is poorer in water and richer in solid matters than in the normal condition or in the first stage of starvation.

THE COUNTY COUNCIL AND STREET NOISES.

THE occasion of another election of Metropolitan County Councillors has been fittingly chosen to bring before the public mind the noises, whether called musical or not, which keep the air of London in daily continuous and powerful vibration. Organ-grinders, Salvationists, newspaper criers, costermongers, and a host of evening traders take up in turn or in concert the glee notes of this clamorous medley. Householders, indeed, have long grumbled against the din, but so far the muffled thunder of complaint has been almost lost amid the shriller discords of their tormentors. Now at last objection finds a voice, and it is heard invoking against the nuisance the reforming energies of the coming municipal administration. It is not surprising that street organists have been specially selected as the objects of disciplinary training. Our readers will remember that last year Mr. Jacoby endeavoured to induce Parliament to restrain this nuisance. From some cause, however, whether on account of more pressing business or from a feeling that the law had already spoken to the point with sufficient clearness, the motion was not carried. We are among those who hold that this result was not entirely satisfactory. We feel that under present conditions the monotonous grinder, breadwinner of a sort though he be, certainly enjoys too much liberty. "Moved on" by the householder, he may return again and again to annoy the victim of his mechanical melodies. Disturbance of the sick, a point of much importance, or of occupation, will at all times justify his removal, but it is enough that he exhibits a technical conformity. This done, he and his opponent may repeat the performance with circus-like precision as often as desired.

Digitized by Google

Some remedy is clearly called for in the circumstances. What we ask for is not, indeed, the total repression of even the organ-grinder's calling, however acceptable to many this might be, but some power of compelling his retreat to a sufficient distance and of forbidding his return during the same day. A like right of restraint might well be exercised in the case of all other classes of street musicians, Salvationists and others, and of newsboys. Their position is by no means the same as that of ordinary tradesmen and costermongers, and such a power of controlling their enterprise as we have indicated may therefore very suitably and fairly be found for a long-suffering public by members of the County Council.

SCARIFICATION OF THE OS UTERI IN CHLOROSIS.

DR. J. CHERON recommends scarification of the os uteri in chlorosis, and points out that this treatment has been highly spoken of by Schubert and others. The amount of blood to be drawn is about one gramme to every kilogramme of body weight. According to the above observers these slight bleedings greatly increase the number of red corpuscles and the amount of hæmoglobin in the blood. Dr. Cheron, in making use of scarification of the os in the treatment of old-standing disease in chlorotic patients, found that the general health as well as the local conditions improved. In many cases an analysis of the blood during and after treatment showed continuous improvement after each scarification. In chlorotic patients congestion of the womb is habitual, and it is easy to obtain forty to sixty grammes of blood at one operation. This local treatment seems likely to be of great benefit to chlorotic women, and it is easy to understand that it would be performed much more readily than venesection. The scarification, if done with antiseptic precautions, is not accompanied by risk.

DIPHTHERIA AT MONMOUTH.

As the result of the investigation into the cause of diphtheria in the girls' high school, it is stated that only very trivial faults of sanitation could be discovered. This negative evidence as to matters of drainage is by no means unusual. It is now stated that the whole system of sewerage and drainage of the town is to be examined and reported on by an expert engineer. Whatever may be the relation, if any, between the present system of drainage and the diphtheria, it is to be hoped that the occasion will be utilised to put this and other matters relating to health on a more satisfactory footing than heretofore.

ETIOLOGY AND PATHOGENESIS OF PERICARDITIS.

DR. ALFREDO RUBINO, editor of the *Riforma Medica*, has presented to the University of Naples, as a thesis for recognition as Lecturer on Special Medical Pathology, an interesting work on the etiology and pathogenesis of pericarditis, based on a large number of experimental observations which he has recently carried out in the laboratory attached to Professor Cantani's clinic. The general object aimed at was to ascertain whether simple injections of a suitable virus into the circulation are capable of producing pericarditis with or without some predisposing cause, such as an injury to the pericardium. Also whether such injections into the pericardial cavity, or the application of cold or other irritants alone, are capable of setting up pericarditis. First, a number of rabbits were subjected to injections into the venous circulation of pure non-diluted cultures of staphylococcus aureus and staphylococcus albus; but in no case was there any sign of pericarditis even as a secondary effect of violent inflammation in other organs; no multiple abscesses of the heart muscle, as described by Fraenkel as being produced under similar circumstances, were met with. When, however, the culture of pyogenic cocci was injected directly into the pericardium there was invariably pericarditis set up. Experiments were next made on animals which had been subjected to injury of the pericardium inflicted by the actual cautery applied over a small area of the external surface laid bare for the purpose, or by puncture with a carefully sterilised needle, these injuries not being of themselves sufficient to produce pericarditis. Here the injection of pyogenic cultures into the venous circulation resulted frequently in pericarditis. Similar results were obtained when the cardiac region had been reduced to a low temperature by the prolonged application of a bag containing ice and salt. Finally, blows on the thorax were shown to be capable of acting as predisposing causes, permitting the entry of pyogenic bacilli circulating in the blood into the pericardium.

THOMSEN'S DISEASE.

Dr. C. L. DANA showed at a recent meeting of the New York Neurological Society a man thirty-three years of age presenting the typical phenomena of this disease. The family and personal history of the patient were good. At the age of seventeen weakness of the muscles was first noticed, and three years later the patient found that after clenching the fists he was unable to open them. The affection had gradually become greater and more extensive, until the only muscles not involved were those of the thighs and upper arms. The myotonia was most marked in the forearm and leg muscles, the tendon reflexes were only obtained with difficulty, and there was no sensory disturbance. The reaction to galvanism was slightly increased, that to faradaism normal. Dr. Dana expressed the opinion that the phenomena were confined to the muscles, and that the disease was a purely muscular one.

FOREIGN UNIVERSITY INTELLIGENCE.

Algeria.—Dr. Texier, Professor of Medical Pathology, has been appointed Director.

Breslau.—Dr. A. Kast of Hamburg has been appointed to the Professorship of Medicine, with charge of the medical clinic.

Giessen.—Professor Konrad Eckhard, senior of the Medical Faculty in Giessen University, celebrates his seventieth birthday to-day.

Halle.—Dr. Graefe, Professor of Ophthalmology, though he had intended to retire at the close of the current winter session, has, in consequence of repeated requests on the part of both the Medical Faculty and the Minister of Instruction, consented to remain.

Havana.—Considerable excitement has been caused amongst the members of the Medical Faculty by a proposal of the Spanish Minister of Foreign Affairs to take away the power of the University to grant the degree of Doctor of Medicine, thus reducing it to the position occupied by Barcelona, Zaragossa, and other Provincial Faculties in the Peninsular which can only grant a licence, the Central or Madrid University being alone empowered to grant the doctorate. A petition has been got up in Cuba, and telegrams despatched to a number of influential persons in Spain begging them to endeavour to persuade the Government to reconsider their proposal.

Madrid.—Dr. Santiago Ramón y Cajal, Professor in the Faculty of Medicine of Barcelona, has been recommended by the jury, after competitive exercises, for the post of Professor of Histology.

Stuttgart.—Dr. Scheurlin has been recognised as *privat-docent* in Hygiene and Bacteriology.

Digitized by Google

Vienna.—In consequence of the illness of Professor Kahler, his assistant, Dr. Kraus, is delivering his lectures.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Kopp, Professor of Chemistry in Heidelberg.—Dr. Moritz Altmann of Berlin, at the age of seventy-seven.—Dr. Vailhé, formerly *professeur agrégé* in Montpelier.—Dr. Francisco de P. Campá, Professor of Midwifery and Gynæcology in Barcelona.—Dr. Johann Wagner, Professor of Anatomy in the University of Kharkoff.—Dr. Barthez de Marmoriéres, a French authority on children's diseases, in his ninetieth year.—Dr. Hermann Aubert, Professor of Physiology in the University of Rostock. His investigations covered a wide range, and included much zoological work, physiological optics, the action of the heart, &c. He also wrote a pamphlet on "Shakespeare as a Doctor." He had been on the Rostock staff since 1865, having migrated thence from Breslau.

A MEETING of the Special Committee appointed at the request of the National Leprosy Fund to consider the report of the Leprosy Commissioners who have recently returned from India was held at the India Office on March 1st. As our readers will remember, the College of Physicians deputed Sir Dyce Duckworth and Dr. Heron, and the College of Surgeons Mr. Hutchinson and Mr. Macnamara, as their representatives, the Hon. G. N. Curzon, M.P., and Mr. E. Clifford being the members nominated by the Fund.

WE are informed that Frederick Needham, M.D. St. Andrews and Medical Superintendent of Barnwood Hospital for Insane, Gloucester, has been offered, and has accepted, the post of Commissioner in Lunacy, rendered vacant by the appointment of Dr. Thomas Clifford Allbutt as Regius Professor of Medicine to the University of Cambridge.

THE German Emperor has received the report of Professor von Bergmann on the building on the Langenbeck House, and has presented a bust of the late Empress Augusta, who was much interested in the enterprise and in medical affairs generally, as its first ornament.

MR. WYNDHAM R. DUNSTAN, M.A., F.I.C., F.C.S., University Lecturer on Chemistry, Oxford, and Professor of Chemistry to the Pharmaceutical Society, has been appointed Lecturer on Chemistry at St. Thomas's Hospital, in the place of the late Dr. Albert Bernays.

Pharmacology and Therapeutics.

DIURETIN.

GHILLANY calls attention to the property possessed by diuretin of absorbing carbonic acid from the air and so becoming insoluble. He recommends that for dispensing purposes a solution of the drug in distilled water should be kept in well-stoppered bottles.

SOLUBILITY OF SALICYLIC ACID.

To increase the solubility of salicylic acid in water the addition of 1 part of acid to 100 parts of glycerine and 150 parts of water gives, it appears, the best results. This mixture is clear and miscible with water without any alteration.

DERMATOL.

Glaeser, in his second communication to the *Centralbl. f. Gyn.*, 1891, on the action of dermatol, gives it as his opinion that it cannot take the place of iodoform. The latter gives especially good results in the treatment of suppurating wounds, with sloughing, whilst dermatol is recommended in the treatment of recent wounds caused by sharp instruments, and in healthy cavities after suppuration. Dermatol is also useful in laparotomy, in operations for prolapsus uteri, and fistula, and is of great service in the treatment of ruptured perineum immediately after confinement, and in plugging the uterus.

METHYLENE BLUE.

A case of retinitis, due to acute Bright's disease, has been treated successfully with this drug in France by Dr. Gillet de Grandmont. He gave it to a patient whose urine contained a considerable quantity of albumen, in doses of two centigrammes three times a day. It caused a marked improvement, the renal symptoms abated, and the retinitis disappeared so rapidly that the sight was normal in four days. Was this a coincidence, or was the improvement due to the milk diet, which, in all the reported cases, has been strictly adhered to? Methylene blue is excreted by the kidney, and has the curious characteristic of turning the urine a deep green. Dr. G. Paul proposes to take advantage of this property to produce a moral effect upon hypochondriacs and malingerers. A dose of from five to ten centigrammes gives rise to decided colouration of the urine without causing any other symptom.

EXALGIN IN CHOREA.

Dr. Löwenthal, in a recent number of the *Berliner Klin. Wochenschrift*, publishes the results of the treatment of chorea by this drug. Thirty-five cases were treated, and the results on the whole were good. In the majority of instances it was found that the sooner treatment was commenced after the onset of the illness the more efficacious was the drug and the more rapid was recovery, but in a few bad cases, in spite of a regular use of the drug, the patient became worse for the first two weeks, but improved subsequently. No severe toxic symptoms were produced, but in a few cases headache, malaise, and vomiting followed, and in three there was distinct jaundice. The dose given was usually from one and a half to three grains, and in most cases improvement followed after from sixty to ninety grains in all had been administered. The conclusion drawn is that exalgin, like many other drugs, is efficacious in chorea, but that it has no specific action in this disease.

SALOPHENE.

Salophene, prepared by F. Bayer and Co., is a derivative of salol. It is obtained by treating para-nitrophenol with salicylic acid, reducing the nitrophenol by means of zinc and hydrochloric acid into an amide, and acting upon this with acetic acid. Salophene contains about 50 per cent. of salicylic acid, and exists in the form of thin scales, tasteless, inodorous, and with a neutral reaction. It is almost insoluble in cold water, and only slightly so when warmed. Upon the addition, however, of an alkali it readily dissolves. It is very soluble in alcohol and ether. It burns with a smoky flame, leaving no residue. In the stomach salophene breaks up into salicylic acid and acetyl-para-amido-phenol. These substances are excreted by the kidney, and can be found in the urine. Salophene, owing to the presence of amido-phenol, is less poisonous than salol. According to Guttmann, it is a valuable remedy in articular rheumatism, given in doses of from four to six grammes a day in pill or in the form of compressed tablets.

HÆMOL AND HÆMOGALLOL.

Hæmol and hæmogallol of Merck, prepared according to the directions of Kobert, are obtained from blood. Hæmol is a brownish-black powder, and hæmogallol a reddish-brown. The introduction of these substances into therapeutics rests on the fact that the derivatives of the colouring matter of blood, obtained by the action of reducing agents, have a hæmatopoietic action both in health and disease. They are given in capsules in doses of from 0·1 to 0·5 gramme during the day. Healthy persons are able to take as much as 1 to 5 grammes of hæmogallol. Hæmol contains traces of zinc left by design. The zinc is beneficial in slight lesions of the stomach, which might result in ulcer. Given in the form of hæmol the zinc loses its caustic action, and does not cause nausea.

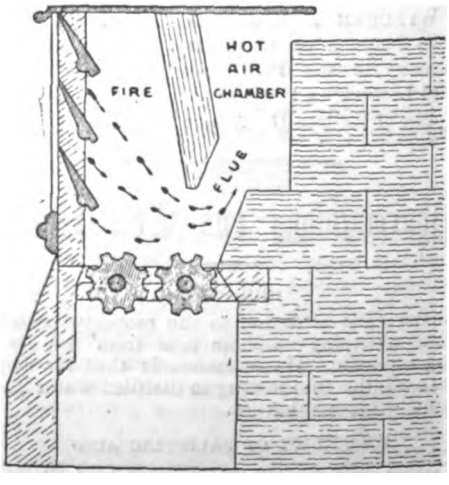
THE LANCET
Analytical Sanitary Commission.



SECOND REPORT ON
PERFECT COMBUSTION AND SMOKE PREVENTION.

THE greatest and most important city in the world is offering at the present moment three problems of colossal magnitude for her people to solve. First, there is the better treatment of sewage with a view to its utilisation; second, the desirability of a more efficient and pure supply of water; and, third, the prevention of smoke and fog. The question of the disposal, though not the utilisation, of sewage was the subject of legislation some years ago, and the water-carriage system at present in use is the outcome of it. Successful as this system has been in effecting the mere removal of sewage from our dwelling-houses, on the principle of "out of sight out of mind," yet we are bound to admit now that, owing to excessive fouling and pollution, the river Thames, into which the sewage is discharged, and upon which we depend so largely for a supply of water, is fast threatening to become a deadly source of evil to the metropolis. All attempts to utilise what must one day prove to be the valuable agricultural constituents of human sewage have practically failed. An increased and purer supply of water for London is a subject which has lately been occupying the serious and earnest attention of the County Council. While, therefore, these two problems, from their pressing importance, have urged themselves upon the notice of our ruling bodies, the solution of the third—namely, that of dealing with the fog and smoke nuisance—has to a great extent been left to and taken up by enterprising individuals who are tempted by the promise of large returns to investigate this subject. The reply given by the Marquis of Salisbury to Viscount Middleton in the House of Lords three weeks ago contained but faint hope of the question being seriously taken up by the Government, although the noble lord expressed the opinion that only legislation of a drastic kind could be expected to deal adequately with the evil. There is promise now, however, of a select committee being soon appointed, and the chances are that such a body will arrive at the results of their inquiry with quicker despatch than if it were submitted to a Royal Commission.

The possibility of lessening to a very great extent the discomfort, not to say injury to health, occasioned by the frequent visitation of fog has long been a matter under discussion. London from climatic causes will always be subject to mist or fog, but it is surely unreasonable to suppose that it is impossible to devise a means whereby the quantity of soot with which our fires constantly load the heavy winter mists may not be to a great extent reduced. It must not be forgotten that unless our system of domestic heating becomes entirely changed we have for the nonce to deal solely with one kind of fuel—namely, common coal. Our supply of coal is practically as abundant as ever it was, and there is no reason to fear that our resources are likely to fail for years yet to come. This being so, it is to the improved consumption of coal as fuel that we must turn our attention, and to consider how far practically the evil of fog and smoke may be remedied by adopting grates of a certain construction as a means whereby perfect combustion and the production of smokeless and innocuous products may be ensured. One difficulty, however, would seem at once to present itself. If a grate were shown and demonstrated to be one which effectually consumes its smoke, only particularly drastic legislation, as the Premier expressed it, could enforce its general adoption. This would amount to a severe impost upon the people; but on the other hand, due regard must be paid to the fact that where perfect combustion takes place, and where, therefore, smoke and soot are not produced, there a distinct economy is also effected in the consumption of fuel. Soot, for example, represents, weight for weight, the fuel value of coal itself, seeing that, according to the analysis shown below, it contains no less than 70 per cent. of carbon. The economy, therefore, in fuel thus effected would contribute in no small degree to lighten the burden involved by the necessary outlay. It seems pretty well established, then, that as long as coal is to be our source of heat, and as long as the present system of utilising it as a source of heat is adhered to, we must look for a solution of the smoke and fog difficulty in the universal adoption of a grate that will burn the coal perfectly and economically, and yet be so constructed as to meet perhaps one of the most formidable of obstacles—namely, that of sentiment. It is hardly to be anticipated that a closed stove or a stove heated with gas or even electricity, however perfect its working may be, will ever replace the homely fire of glowing coals, which in the English mind will always lend a charm to the cold and dreary days and nights of winter.

With these views strongly impressed on our mind, it has always been of interest to us to scan from time to time that horizon upon which so many improved designs of the kind referred to appear, that we might study them, and submit them, if need be, to practical tests, and afterwards to give prominence to any device which we may find on experiment to give promise of grappling with the difficulty. Thus we may reasonably hope to render signal service to the great cause of public health. Last year (*vide* THE LANCET, March 21st, 1891, p. 682) we placed on record the results of our experimental trials with a stove invented by M. de Clausen, a Russian civil engineer. According to our experience this invention was the nearest approach to the great desideratum required in combustion; there was no escape of unburnt gases or of unconsumed carbon, the consumption of fuel was remarkably small, while the practical yield of heat was not far short of that demanded by theory. The principle, as it was then shown, could be applied to locomotives, marine boilers, and to furnaces for factory engines. The stove, being of the closed type, would probably be more favourably accepted as applicable to industrial and manufacturing purposes than for the purpose of domestic cooking or for heating drawing-rooms. In the early part of this year a newly designed kitchen range, said to consume its own smoke and to effect an important economy in the consumption of fuel, came under our notice. From an inspection of the plans which had been submitted to us we felt that the system was, at any rate, worthy of investigation, and it was decided to send one of our Special Commissioners to Bradford, where the range could be seen in actual operation, and where a series of experimental observations could be conveniently made. All this has been recently done, and the results gained form the subject of the present report.

The inventors and elaborators of this new system of firing, Messrs. H. Leggott and E. Marsh of Bradford, could hardly have hit, we imagine, upon a simpler arrangement than that shown in the annexed sectional plan, by

which perfect combustion and smoke consumption are said to be effected. It barely needs explanation. Let it be sufficient to point out the main differences existing between this and the ordinary range. Instead of rigid iron bars in the front of the fire there are to be found three iron "louvres," as they are termed, which

Digitized by Google

may be opened and closed exactly like a venetian blind by means of a lever outside. The bottom of the fire-box consists of two grooved or cogged rollers, which, turning inwards by a simple arrangement, serve to stir the fuel and remove ash. The space occupied by the arrows indicates the fire place proper, while they also show the direction taken by the incoming air. The fire chamber is divided into two parts by a fireproof septum of brick suspended from and fastened to a fixed iron plate at the top. The fireplace consists, in fact, of a V-shaped tube into which air is admitted *downwards* through what we may call, for the sake of explanation, "the venetian blind," or properly the louvres. The fuel is put in at the top, as in an ordinary range. The present experiments were conducted with a kitchen range

similar to that shown in the second illustration, but the system can be applied to almost any kind of furnace, such, for example, as those for heating large boilers, big ovens, hot-water apparatus, &c., and we believe that the inventors have recently constructed a stove and grate suited to the wants of a dining-room, drawing-room, or office.

The way the fire is lighted is instructive, and not without an element of interest, as it is done in a way exactly the reverse of the usual method. It was odd to see the paper, with the wood, placed on the top instead of underneath the coal. On lighting the paper the flames were almost immediately sucked powerfully downwards upon the wood, which in its turn ignited, and subsequently the underlying coal. In a very short space of time the fire was well alight, and the roar of the flame was surprising. The rate of combustion is under complete control by the joint use of the louvres and the dampers. As this was considered a moment favourable to the production of smoke—that is, soon after lighting—we proceeded to inspect the chimney. A thin, almost invisible, smoke in nearly imperceptible quantity was seen to issue. It ceased entirely after a few minutes, and, in fact, ceased for the day. Even this small production of smoke, consequent on first lighting, could be avoided by regulating the stove to slow combustion the last thing at night and charging it with a small quantity of fuel. The next trial was severe enough; indeed, to call it the *experimentum crucis* would be no misnomer. While the fire was burning brightly small coal along with dust was thrown upon the red-hot mass. Everyone is acquainted with the result of this procedure in an ordinary range; dense volumes of opaque smoke are produced, resulting from the partial distillation of the coal and the cooling down of the products as they are evolved into the air. As soon as the small coal was thrown on the fire the chimney was again watched, but scarcely a semblance of smoke was visible. This experiment illustrates excellently the theory advanced, amongst others, by M. de Clausen, that failure of combustion is due not to want of air but to the absence of a sufficiently elevated temperature, under which condition the combination of carbon with oxygen can only produce the complete product, carbonic acid (CO_2). No doubt the moment smoke is formed in this range it is dragged down with air through a red hot mass, where complete combination or combustion is effected. In both these experiments samples of the gases issuing from the fire up the flue were analysed. The results appear below. It is well to state at once that coal in small pieces, or "nuts," or even dust, is the kind of fuel best suited to the range. Lumps of coal such as we throw on our ordinary fires produce smoke because the existing temperature is for a time greatly depressed, being absorbed in part by the cold fuel and by the dispersion of its hygroscopic matter. In addition to the reduction of the heat temporarily, the thick bed of fuel impedes the draught, and sufficient air cannot enter to effect a consumption of coals adequate to the generation of the amount of heat required. The portion of air which traverses the fire is deoxidised by the ignited fuel on the bars, and no oxygen for a considerable period can come into contact with the mass lying upon that which is burning; but although in this way it does not contribute to the pyrometrical effect, the temperature of the ignited mass and the heated gases permeating it from below cause a distillatory change by which the whole of the available hydrogen, together with a large percentage of the carbon, is expelled as hydro-carbon gases, which escape combustion. When, on the other hand, the fuel is in relatively small particles, the oxygen of the air has a better chance of coming into intimate contact with every particle of fuel during ignition, and this being assisted by the ventilating action of the louvres, complete combustion is at the outset established.

The kind of coal used in the experiments made, and which is recommended in practice as best, is called in Yorkshire "smudge"—an inferior class of dust coal—and ordinary "nuts," or slack. The former is delivered in Bradford at 4*s.* 6*d.* per ton, and the latter at 12*s.* 6*d.* per ton. The samples were duly submitted to analysis, and the following results give some idea of their composition and quality:—

	"Smudge."		Nuts.	
Moisture	4·40 per cent.		4·62 per cent.	
Carbon	70·10 "	In dry coal.	74·80 "	In dry coal.
Hydrogen	5·20 "		4·94 "	
Nitrogen	1·41 "		1·65 "	
Sulphur	1·40 "		1·25 "	
Oxygen	13·75 "		9.99 "	
Mineral matter	8·14 "		7·37 "	

Neither sample possesses qualities of special value; they contain a large proportion of mineral matter, although the quantity of sulphur is not excessive. The "smudge" is, as might be expected, less rich in carbon, contains a higher amount of useless oxygen and more mineral matter. The difference in quality between these coals and good house coal is apparent in the following analysis made on the occasion of a previous investigation.

Moisture	4·12 per cent.	
Carbon	79·95	Per cent. in dry coal.
Hydrogen	5·45	
Nitrogen	1·80	
Sulphur	2·00	
Oxygen	7·73	
Mineral matter	3·07	

Ordinary house coal is evidently richer in valuable carbon, contains a much smaller amount of mineral matter, and less useless or dead oxygen. The range is thus shown to be capable of burning the inferior kinds of coal, costing, when delivered in Bradford, 4*s.* 6*d.* per ton, which in normal times means about 12*s.* per ton at the London depots.

Turning next to the gases passing out of the flue, several samples were analysed on the spot directly they were entrapped. The gases were collected by means of an approved aspiratory arrangement, and in order to determine whether they contained any carbonaceous particles, a plug of cotton-wool was placed in the tube through which the gases were passing to the aspirator. At the conclusion of the experiments the wool was examined, and was found to have acquired a greyish-brown tinge, whilst no particles of carbon could be observed. If this experiment were repeated with an ordinary range, it is almost needless to add a plentiful deposit of sooty particles would be obtained. On analysing the gases the following results were gained:—

	No. 1. Soon after lighting; gases taken from right hand damper.	No. 2. From same place; louvres closed; coal well alight.	No 3. Gases taken from flue above mantel-shelf.
CO_2	1·00 per cent.	2·00 per cent.	1·00 per cent.
O	18·60 "	17·40 "	18·00 "
N	80·40 "	80·60 "	81·00 "
SO_2	Traces	Traces	Traces
CO	None	None	None

The low proportion of carbonic acid gas (CO_2) in these samples was, it must be admitted, disappointing. If complete combustion of coal is taking place one would expect to find a far higher proportion of this gas. In no instance, however, it should be remarked, was the presence of carb n

Digitized by Google

monoxide (CO), or sulphuretted hydrogen detected. The explanation of the small quantity of CO_2 was not far to seek. On account of the draught produced it was found, in spite of many precautions, that air was being admitted into the gases before they were collected, through the crevices incidental to the construction of a kitchen range and situated below the point where the samples were being taken. So the samples of gases analysed were evidently admixed with a large proportion of air. That this was the true explanation was confirmed by the fact that the flame of a lighted taper applied to the crevices was immediately sucked in by the in-rushing air. It was accordingly decided to collect the gases lower down, immediately over the fire, although the same difficulty of obtaining a fair sample, but to a less extent, presented itself. The following figures express the results:—

	No. 4. Gas taken from immediately over fire; louvres well open.	No. 5. Gas from same place as last; louvres partly closed; fire recently repaired.
CO_2	9·00 per cent.	7·00 per cent.
O	11·30 ,,	13·00 ,,
N	79·61 ,,	80·00 ,,
SO_2	·09 ,,	Not determined.
CO	None.	None.

At once the proportion of carbonic acid CO_2 rises, and no doubt would rise still higher if the arrangement for sampling the gases could be made still more perfect. It is a significant fact, however, that in no single instance were incomplete products of combustion like carbon monoxide (CO) or sulphuretted hydrogen (H_2S) obtained. In addition to the above analyses samples of gases were brought to THE LANCET laboratory and analysed there, with the following results. They were all taken from just above the fire:—

	No. 1.	No. 2.	No. 3.
CO_2	9·17 per cent.	9·30 per cent.	10·02 per cent.
O	10·30 ,,	10·08 ,,	9·28 ,,
N	80·53 ,,	80·62 ,,	80·70 ,,
CO	None.	None.	None.

Next a sample of the deposit from the flues after the stove had been working several days was collected. The following analysis (No. 1) gives an idea of its composition; and that they may be compared an analysis (No. 2) of flue deposit or soot produced in an ordinary range is appended:—

No. 1.		
Moisture	0·70 per cent.	
Carbon	7·20 ,,	Per cent. in dry deposit.
Hydrogen	0·23 ,,	
Mineral matter	89·15 ,,	
Nitrogen (partly as ammonia) and oxygen	3·42 ,,	

No. 2.		
Moisture	6·68 per cent.	
Carbon	76·76 ,,	Per cent. in dry soot.
Hydrogen	— ,,	
Mineral matter	16·68 ,,	
Nitrogen (ammonia)	6·56 ,,	

Now, as coal contains the same amount of carbon (from 70 to 80 per cent.) as the soot produced in the flues of an ordinary range, according to the results of the above analysis it follows that soot represents its own weight of coal or fuel lost and wasted. But the flue deposit produced in Mr. Leggott's range contains only 7·2 per cent. of carbon, so that it may fairly be assumed that the saving and utilisation of fuel from this cause are at least, and probably more, than 60 per cent. The deposit is greyish brown in colour, and appears to consist mainly of mineral matter derived from the ash of coal. This is an eminently satisfactory result, and demonstrates clearly not only the fuel economising effect of the system, but also that the production of soot is practically *nil*.

By reverting again to the illustration of the sectional plan the principle of the system may be examined, and an explanation be sought to account for this so far satisfactory action. The fire-box is V-shaped, and the air is admitted *downwards* through a mass of *small* glowing coal. Thus a sufficiency of the oxygen of the air is brought into intimate contact with the combustible constituents of the coal. This would effect at the outset complete combustion. But it is well known that CO_2 passing over more red-hot coal is reduced to CO, which, coming again in contact with oxygen at a *sufficiently elevated temperature*, burns into and reproduces CO_2. But whether or not carbon monoxide is first formed in this range, there can be no doubt that it is ultimately burnt completely into the dioxide, for in no single instance was carbon monoxide or other incomplete product of combustion detected in the effluent gases. The V shaped arrangement would seem in some measure to play the part of a gas retort. The coal is distilled by the heat of its own combustion in the front limb, and the gases or distillation products are compelled by the draught set up to go downwards admixed with air, through an incandescent mass, out of which they emerge into the limb at the back, and now elevated to the required temperature, they are burnt, and complete combustion takes place. It is well known that perfect combustion can only happen when the in-rushing air is raised to a sufficiently elevated temperature. The combination of the right quantity of oxygen with carbon in a sufficiently elevated temperature can then only produce CO_2. A sufficiency of air and a proper elevation of temperature are conditions which Mr. Leggott seems to have secured by the adoption of the device which characterises his invention. The angle of the V acts as a smoke trap, and, being always incandescent, raises the mixture of air and hydrocarbons to that temperature at which only their perfect combustion can be effected.

It is stated that where these fires have been in use the saving in cost of fuel has been from 50 to 200 per cent. Our Commissioner made it his business while in Bradford to inspect a range fire that had been at work for some time in the kitchen of a coffee tavern where a large amount of cooking is done. This range is lighted at 4 30 A.M. every morning, and is kept going till eleven o'clock at night, and, in spite of constant work, it is declared to cost not more than 2*s.* 6*d.* per week—that is, with fuel costing, say, 5*s.* a ton. At the time of our Commissioner's visit all manner of cooking was going on, the fire was working perfectly, and no smoke could be seen issuing from the chimney, even when the severe experiment of charging with fresh small coal was tried. In the same establishment a steam boiler for heating purposes is worked on this principle and with similarly satisfactory results, both fires, it is declared, costing only 7*s.* 6*d.* per week for fuel, whereas before the boiler alone cost 15*s.* The range may be worked under perfect control, at a maximum or minimum heat, with equally good results as regards combustion. The maximum heat produced by suitably arranging the dampers and louvres is very great, the roar of the flames is remarkable, and probably the full pyrometrical effect of the fuel is obtained. Some heat is of course carried away up the chimney by convection, but it cannot be said to be wasted, for it is just this heat that is necessary to maintain an essential draught through the system. The coals can be seen glowing, and the roasting of meat in front of the fire, it is said, may be easily effected. A thermometer placed within six inches of the louvres showed a temperature of 320° F. (160° C.) Yet the rate of combustion can be so regulated that on putting a shovelful of coal on the last thing at night, the louvres and dampers being adjusted for slow combustion, a bright fire may be obtained in the morning in a few minutes by simply readjusting them. The trouble of lighting a fire is thus avoided, and the risk of a preliminary, though small and insignificant, escape of smoke reduced to a minimum.

LUNATIC ASYLUM REPORTS FOR 1891.

Glasgow Royal Asylum, Gartnavel. — Dr. Yellowlees reports that the admissions of the year were entirely of the private class. "The admission of parish patients," he says, "has finally ceased, and the institution is now fulfilling its true function in affording the needful care and treatment to private patients from all grades of society, and in affording them to those of the least affluent classes at rates which would be impossible if profits had to be made and dividends paid." The recoveries numbered fully 38 per cent. of the admissions; and this is considered to be a satisfactory result, regard being had to the hopeless character of many of the new cases. The death-rate was 8·5 per cent. of the average number resident. Three died within a week of admission, and ten out of the forty-two deaths were referable to influenza and its complications. The following remarkable case recorded by Dr. Yellowlees is well worth special notice:—"A lady aged forty-four was admitted in January, 1876, labouring under melancholia, with delusions of dread and

Digitized by Google

suspicion, especially that her food was poisoned. In September of the same year her refusal of food became so obstinate and her resistance so determined that it was necessary to resort to the stomach-tube. Every attempt to feed her otherwise failed. She could not be made to swallow even a teaspoonful of water, but allowed it to pass into the air passages rather than yield; and she was fed with the tube three times daily till May, 1885, a period of *eight years and eight months*. During all this time she was very miserable, and kept continually repeating the doleful refrain, 'You're going to kill me; you're going to kill me. I know you're going to kill me.' The spell was broken almost by accident. Entering the ward when she was just about to be fed, I made another attempt with the spoon. In the struggle her chair was tilted backwards. In terror of falling she forgot for a moment to resist, and suddenly swallowed the spoonful of beef-tea I had put in her mouth. She seemed surprised and shocked, but the advantage, once gained, was followed up. By very slow degrees she was made to swallow all the beef-tea which had been prepared for the tube, and was then told that, having taken it once, she must take it always. Many a tedious struggle it cost the nurses, but at length they triumphantly reported that she had used the spoon with her own hand. From this point recovery, though slow and gradual, was uninterrupted. She refused to leave the infirmary ward and the nurses to whom she owed so much, became useful, cheerful, intelligent, and full of interest in others, and was discharged recovered in February, 1891, after a residence of over fifteen years. She is still quite well, and the recovery seems not only complete, but permanent."

Aberdeen Royal Lunatic Asylum.—Dr. Reid, the superintendent, reports that the average number resident was 630—202 private, and 428 panper lunatics. The total number of cases under treatment was 840. The admissions numbered 226, being an increase of 1 on the number for the previous year. The discharges were 149, a percentage of 38·9 on admissions. The number of deaths was 45, or 7·1 per cent. on the average number resident. The following interesting case is given as illustrating the peculiar propensities of some patients. A female, aged forty, was admitted on June 23rd in a weak and emaciated physical condition, labouring under active melancholia, and with a fractured arm caused by her having thrown herself from the second flat of a tenement house. Great vigilance had to be exercised owing to her suicidal tendencies. Everything went on as satisfactorily as could have been expected until July 27th, when she was seized with great vomiting and pain in the epigastric region. Without entering on full medical details it may be briefly stated that, from the aforesaid date till the second week of October, the patient passed no fewer than 125 pins and sewing needles, with, in addition, many darning needles and hairpins; also a pair of spectacles in pieces and a crochet needle. Although she had lost much flesh, at the end of October recuperative power set in and she was slowly and gradually recovering both in body and mind, when an attack of pneumonia supervened, and she died on Dec. 13th. Dr. Reid points out numerous defects in the main structure of the asylum, and he says the directors of the asylum have been actively engaged for a considerable time past in investigating them. The Commissioners, while speaking highly of the ability and success with which the management is carried on under the many difficulties, hope that the new hospital block will be commenced without delay.

THE EDINBURGH ASSOCIATION FOR THE PROMOTION OF REFORM OF MEDICAL EDUCATION.

THIS Association has presented a second statement to the Scottish Universities' Commission dealing with Draft Ordinance General, No. 10, and referring to the duties and emoluments of professors, lecturers, assistants, or other persons engaged in medical teaching in the University of Edinburgh. The statement points out that in 1831, after the institution of the present chairs of surgery and pathology, the number of professors in the University was thirteen, and that the number had remained at that until the present time. In 1831 there were 810 medical students, the number falling in 1845-46 to 330, but in 1889-90 it had risen to 2003. During the same period the range of subjects requiring the attention of students had risen from fifteen courses of lectures and four practical classes in 1859-60 to seventeen courses of lectures and thirteen practical classes in 1891-92. Owing to the number of students the practical classes have sometimes to be repeated eight times in the year. The increase in the range of study now necessary has arisen from the enormous development and differentiation of the medical sciences. Subjects which in 1831 were perhaps well within the grasp of a single teacher have now become a group of subjects, the due exposition of each of which requires the undivided energy of one person. Under the circumstances, it might have been expected that provision would have been made to give effect to the differentiation which has taken place within each subject, and to meet the need of instruction in the additional subjects referred to; but nothing of the sort has, in any thoroughgoing sense, been effected. Instead of differentiation, what has been done is the addition to the systematic lectures of practical and tutorial classes under the conduct of the single professors in each department, the result being that differentiation in teaching remains largely unprovided for, and that to a greater extent even than is carried out by the extra-mural school or by the smaller foreign universities.

The Association then points out that original research has fallen behind, and that the functions of a University are not merely to communicate the results of scientific progress made elsewhere, but to contribute to that progress by its own efforts. The increase in the demands made upon the professoriate has been met in other institutions by an addition to the professorial staff, but this has not been done in the Edinburgh University. In forty foreign schools specified by the Association there is on an average 25·6 professors in each school, against 12 professors in Edinburgh. Attention is further drawn to the fact that in Edinburgh (with 2003 students) there are twelve professors, while in Leipsic (with 944 students) there are 35 professors, and in Strasburg (with 353 students) there are 28 professors. These last, given in detail in the statement, are submitted as moderate examples of specialisation.

Between 1831 and 1892 four lecturers have been added—viz., Diseases of Children, Insanity, Ophthalmology, and Embryology. During the same time about thirty assistants have been appointed, towards the payment of whom the University Court has contributed £1150, while the professors subscribed £2812. These gentlemen have been appointed by the professor, and their dismissal has been in the hands of the professor of each department; they have no special University privileges and no voice in any University governing body. It thus follows that the University has worked its medical school by means of twelve professors (seven of whom are in private practice), five lecturers (of whom four are in private practice), and about thirty assistants, who do the main part of the practical work.

In respect of original research the facilities obtainable at the University are in most cases so defective that investigators are obliged to go elsewhere for working facilities which ought naturally to be found within the University.

The statement then proceeds to consider the financial conditions. The income of the medical side of the University is derived from (1) graduation and matriculation fees and (2) class fees. The former amount to about £8000 a year, and go to the General University Fund, the greater part, however, being returned for the expenses of the medical department. The class fees are paid to the professors directly, and in 1889-90 £23,259 8*s.* 4*d.* were thus received. The emoluments of professors consist of these fees, together with £1620 15*s.* 2*d.* from Endowment and the General University Funds, making a total of nearly £25,000, or a little over an average of £2000 a year. Out of this sum the professors paid in 1889-90 £4537 7*s.* 8*d.* for departmental expenses. The average net incomes of medical professors in the year 1886-87 were in Edinburgh £1620, in Glasgow £907, and in Aberdeen £645, while in the English Colleges and Universities the average is about £800 per annum, without retiring allowances. By the present system the professor in each department is the sole judge of how much money is to be applied out of his total fees for the payment of assistants &c., and how much is to be retained by him as his own income. The opinion of the Association is that this system should cease, and that the fees should accrue to the University and not be personal. The evils of

Digitized by Google

the present system are that some professors have enjoyed net incomes which bear no necessary relation to the work of their chairs, to the standard of corresponding emoluments in other Universities, or even to the incomes of their colleagues in other Faculties; it tends further to discourage the development of those higher branches of teaching which are not in themselves remunerative.

Professors' retiring allowances are next dealt with. The present arrangement is that a professor may, after ten years' service, retire on a pension of one-third of his income, calculated on the average of the five preceding years, and one-sixtieth more for each year up to thirty years, when he may retire on two-thirds of his previous income. The Association expresses the opinion that the mode of adjustment of retiring allowances is now felt to have been an unfortunate one.

Then follow the suggestions by the Association:—

1. That if any equitable means of adjusting the emoluments of the medical chairs can be devised so as to liberate a proportion of the fees for the general purposes of the school, those means should be adopted.
2. That if it prove to be necessary to ask for a special Parliamentary grant, in order to bring about this change without crippling the general finances of the University, every effort be made to secure such grant.
3. That the University Court should be empowered to make, upon the appointment of any professor, extra professor, lecturer, assistant, or other officer of the University, any regulation determining the amount and mode of his remuneration.
4. That the Commission recommend to the University Court that, in determining the amount and mode of the remuneration of any professor, extra professor, or lecturer, the Court follow the principle of allowing a fixed stipend and a proportion of fees, taking into consideration that the duties of some of the chairs are discharged in conjunction with private practice, which is rendered more lucrative by reason of the University appointment. Such remuneration should be subject to revision and readjustment at stated intervals.
5. That all fees paid by students for classes should be paid to an officer of the University Court, and should form a Medical Faculty Fee Fund, to be applied at the discretion of the Court, for the purposes of the Medical School.
6. That the University Court should, in their discretion, allocate the Fee Fund from year to year to payment of professors, of new professors, of lecturers, of assistants, of laboratory and research expenses; to the purchase of appliances for practical classes, and to the expenses of the same; to the payment of any contribution or quota by the Medical School towards the general expenses of administration; to the establishment of a Medical Faculty Reserve and Contingency Fund; to the establishment of a fund for the endowment of new chairs in the Medical Faculty; or to any other purpose incident to the due carrying on and expansion of the Medical School as a part of the University, which the University Court may find to be necessary or expedient.
7. That the University Court be empowered to appoint extra professors of medical subjects. The Association recommends that immediate attention be given to the establishment of extra professorships in the following subjects—namely, an additional Professorship of Anatomy, and also Professorships of Bacteriology, Histology, Chemical Physiology, and Public Health; and that the existing lectureships be raised to professorships.
8. That University lecturers appointed in the medical faculty by the University Court should be appointed for periods of five years, with independent University status, the use of University rooms, apparatus, and museums, and remuneration to be determined by the University Court. That no assistant to a professor should at the same time be a University lecturer. The Association recommends that provision be made for the teaching of surgical pathology, medical physics, pharmacology, and diseases of the tropics, if necessary, by the institution of separate lectureships, and that clinical lectureships be established in gynæcology, fevers, dermatology, and throat and ear diseases, the remuneration being determined according as the lecturer appointed is or is not at the same time engaged in private practice.
9. That the whole teaching staff be paid directly by the University Court.
10. That all teaching appliances and collections in the museum and laboratories should be the property of the University, and be maintained at the expense of the University.
11. That careful consideration be given to the question of avoiding undue increase in the aggregate cost of medical education, and that if the suggestions of the Association be adopted a readjustment of fees should be made.
12. That the accommodation in the New University buildings be readjusted and more fully utilised with the view of providing room for the new teachers proposed.

THE LONDON HOSPITAL.

AT a meeting of the Court of Governors held at the London Hospital on Wednesday, March 2nd, it was announced that the house committee had unanimously decided, on the suggestion of the matron, to increase the holidays of the staff nurses to three weeks in the year instead of two as formerly, as it was now for the first time possible to do so without at all impairing the efficiency of nursing in the wards of the hospital. The chairman (Mr. Buxton, treasurer of the hospital), in moving the adoption of the annual report, referred to the attacks which had been made upon the committee in reference to the question of the nurses. He thought it unfair that a few governors should, against the judgment of a strong managing committee, insist upon some small changes being made. He detailed the statements which had been made by the critics of the action of the house committee in reference to the training of nurses. The training which the probationers received rendered them thoroughly well skilled at the end of their first year, but the certificate of competency was withheld from them until the end of the second year, so that the hospital might have for one year the advantage of their training. In the month of January applications were received from 395 persons for private nurses, of which only forty-two could be accommodated. Only in three instances had complaints been received, and these of a very trivial kind. The management of the London Hospital should be left to the house committee, who had very much more knowledge than the outsiders. No institution could be properly managed if every question of detail was submitted to hostile criticism. It was for the governors to stop it by supporting the committee which they had elected to manage the affairs of the hospital.—Mr. Hunter denied that any attacks whatever had been made on the London Hospital, but he complained that the nurses were overworked, and maintained that many changes were necessary to enable them to carry on the very important work which they had undertaken with justice to themselves and in a proper and efficient way with regard to their patients.—The chairman of the hospital, Mr. E. Murray Ind, said that the criticisms had been doing a great deal of harm to the poor people in the East-end of London by stirring up in the public mind a want of confidence in the management of the hospital. If that went on much longer it must divert from the hospital the funds which were absolutely necessary to carry on the work. Receipts last year fell short to the extent of £25,000. Taking the ordinary receipts and expenditure, there was a decrease of £10,000 as compared with the ordinary income of last year; a large portion of that sum was out of donations. The donations fell £4000 short of the sum of the previous year. This involved a responsibility which the committee did not consider they should be called upon to bear any longer. If the Court of Governors elected a house committee it must be on the clear understanding that the committee manage the hospital and nobody else.—Mr. F. C Costello said it had been suggested that those who criticised the reports of the house committee should be prevented from attending the Court of Governors. The only process by which it would be possible to prevent any governor from raising any reasonable criticism on the reports would be by excluding him from the meeting.—Mr. Ind pointed out that the injurious criticism might be stopped either by the governors passing a vote of censure on the critics, or by passing a vote of confidence in the house committee.—The Rev. Dr. J. F. Kitto suggested that it was also a question of what was seemly or becoming. He moved, as a rider to the report: "That this Court of Governors of the London Hospital, in adopting the quarterly report of the house committee now read, desires to express its unabated confidence in the administration of the hospital, its warm appreciation of the services of the house committee, its cordial and hearty thanks to the officers of the hospital and to the whole nursing staff for their zealous and loyal coöperation with the house committee in carrying out so important a work."—The report and Dr. Kitto's rider were carried unanimously.—The Court then confirmed the appointment of Mr. Dean, F.R.C.S., as assistant surgeon to the hospital in place of Mr. Reeves, who had resigned.

GENERAL PRACTITIONERS' ALLIANCE.

A MEETING of the council of the above Association was held at the offices, Adam-street, Strand, W.C., on the 26th ult., Mr. George Brown presiding.

The following registered medical practitioners were proposed and duly elected members of the Alliance:—Messrs. H. J. Butler, J. Gason (Rome), F. E Flynn, John Murray (Folkestone), H. Pelham Webb, M.B., A. Wilson, M.D., and Edward Blake, M.D. The hon. treasurer (Dr. Hugh Woods) stated that, although no public appeal had been made for subscriptions, the sum of £23 2s. had been received

Digitized by Google

from members of the Alliance and friends towards the expenses connected with the candidature of Dr. Alderson and Mr. Brown in the recent election to seats on the General Medical Council. The hon. treasurer was instructed to convey the best thanks of the Committee to those gentlemen who had kindly contributed towards the election expenses. The President then stated that, this being the first meeting of the Council held subsequently to the complimentary dinner to Dr. Alderson and himself, he could not allow the occasion to pass without expressing his deep obligations to the Election Committee, and especially to Dr. J. W. J Oswald (chairman), Dr. Boyd (hon. sec.), and Dr. Hugh Woods (hon. treasurer), for the great services they had rendered to Dr. Alderson and himself, in promoting their candidature, and which had been successful beyond anticipation. Dr. Alderson expressed himself in similar terms. The President read correspondence with a practitioner in the north of England whose unregistered assistant was reported to be in the habit of signing certificates and appending to his name initials implying that he was duly qualified. The practitioner referred to explained that his assistant held qualifications from a Colonial university, and that he would see that he did not give similar certificates in future.

A letter was read from a provincial member expressing the hope that the Alliance would take some steps in regard to medical aid associations, which, he alleged, were doing serious injury to the practices of medical men in provincial towns. The President stated that he hoped to get information respecting the working of these associations to lay before the Council at a future meeting.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bromsgrove Urban District.—Monthly statistical returns, as regards any but large populations, are, as a rule, very imperfect indications of the true vital statistics of a community; but it may be noted that in Bromsgrove town, where influenza was very prevalent during January, the death-rate for that month reached 83·18 per 1000 living, that rate being only reduced to 71 per 1000 after correction for non-residents. The disease has, according to Dr. Cameron Kidd, shown distinct signs of abatement during the current month.

Hove Urban District.—On the population as taken at the last census, the death-rate for Hove during 1891 was 12·6 per 1000, the zymotic rate being 0·5 per 1000. Notification led to the discovery of 119 cases of infectious disease, of which 52 were removed to the useful hospital at Hangleton, where a new pavilion is in course of erection. As regards sanitary circumstances, we learn but little, except from a return of the inspectors of nuisances, Mr. E. S. Medcalf's own report dealing almost exclusively with vital and disease statistics.

Ulverston Urban District.—The high rate of death during 1891—namely, 22 per 1000—was not due to ordinary zymotic diseases, for Dr. Thompson gives the zymotic rate as 0·7 per 1000 only. The water-supply is unsatisfactory, but is receiving attention; whereas the sewers, scavenging, inspection of slaughter-houses, lodging-houses, &c., are well looked after. With regard to influenza, Dr. Thompson gives his personal experience. He says it nearly cost him his life in 1857; he suffered again severely in 1890, and he has had three attacks during the past year.

Kettering Urban District.—The population of Kettering is now estimated at 20,000, having increased by 8360 during the last decade, and, happily, the death-rate remains as low as 14·6 per 1000; whilst the zymotic rate was only 0·3 per 1000 last year. Scarlet fever cases were reported every month, but by the constant and wise use of the isolation hospital it never made headway, and not a single death occurred from that cause. Typhoid fever has at times been somewhat prevalent in Kettering, and twenty-one cases were reported last year. Here, again, hospital isolation was successfully utilised, and the impure wells with which the disease was associated were closed. As to this, we would hope that increasing efforts will be made to get rid of these sources of danger before, instead of after, they have caused disease. Mr. Dryland has always pressed this point, and he does so again. We trust he will receive every support with regard to a sanitary operation so necessary to the health and well-being of this growing town.

Carlisle Urban District.—According to Mr. William Brown the death-rate for Carlisle during 1891 was 19·0 per 1000 living, the zymotic rate being 1·6, measles and scarlet fever being the main contributors to the latter. Scarlet fever seems to have been extensively prevalent for some time since. From March to December, 1890, 578 cases of this disease were reported, and last year the number was 564. Although the disease is stated to have prevailed chiefly among the working classes, yet only thirty out of the 564 patients were dealt with at the isolation hospital, and this was not because the hospital was otherwise in use, for the total admissions during the year only added eight more to the admissions from all causes. It is difficult to understand this, for it is stated that, as regards patients certified as proper for isolation, the expense of maintenance is—as it should be—borne by the authority. Mr. Brown, in dealing with other questions of interest, refers to the not unfrequent connexion between enteric fever and cattle manure, and he notes that forty-five cases of that disease came under his notice in the period 1882–87 as occurring in association with slaughter-houses, cow-houses, or tripe manufactories. It is difficult to appreciate the significance of this without information as to the general incidence of the disease during the same years on parts of the city not immediately bordering on such places; but the point is one to which attention has been elsewhere directed.

Waltham Holy Cross Urban District.—Mr. J. D. Priest has occasion to refer to some serious defects in the sewerage system, whereby sinking of sewers, retention of deposit, and other evils have been brought about. At the same time he reports that a good deal of sanitary work was done during the year. He strongly urges the provision of some means of isolating first attacks of infectious diseases, and of a disinfecting apparatus. On a population of 6060, the death-rate for 1891 was 16 per 1000 living.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6449 births and 4571 deaths were registered during the week ending Feb. 27th. The annual rate of mortality in these towns, which had declined in the preceding five weeks from 35·4 to 21·1 per 1000, rose again last week to 23·4. In London the rate was 22·4 per 1000, while it averaged 24·1 in the thirty-two provincial towns. The lowest rates in these towns last week were 14·2 in Croydon, 16·6 in West Ham, 17·8 in Huddersfield, and 17·9 in Brighton; the highest rates were 29·9 in Derby, 30·5 in Bristol, 32·9 in Halifax, and 34·0 in Burnley. The 4571 deaths included 426 which were referred to the principal zymotic diseases, against numbers declining from 607 to 383 in the preceding six weeks; of these, 155 resulted from whooping-cough, 123 from measles, 49 from diphtheria, 39 from diarrhœa, 31 from scarlet fever, 28 from "fever" (principally enteric), and one from small-pox. The lowest zymotic death-rates were recorded in Croydon, Norwich, Plymouth, Swansea, and Leicester; the highest rates in Bristol, Cardiff, Liverpool, and Wolverhampton. The greatest mortality from measles occurred in Sheffield, Sunderland, Liverpool, and Wolverhampton; from scarlet fever in Cardiff; from whooping-cough in Newcastle-upon-Tyne, Derby, Blackburn, Wolverhampton, and Bristol; and from diarrhœa in Preston. The mortality from "fever" showed no marked excess in any of the thirty-three large towns. The 49 deaths from diphtheria included 30 in London, 3 in Bristol, 3 in Sheffield, and 2 each in Manchester, Leeds, and Newcastle-upon-Tyne. One fatal case of small-pox was recorded in Liverpool, but not one in London or in any other of the large towns; 10 small-pox patients were under treatment in the Metropolitan Asylum Hospitals, but not one in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of last week was 1198, against numbers declining from 1397 to 1216 at

Digitized by Google

the end of the preceding five weeks; 86 new cases were admitted during the week, against 117 and 82 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 1465 to 450 in the preceding five weeks, rose again last week to 460, but were 39 below the average. The causes of 105, or 2·3 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Birkenhead, Oldham, and in four other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Preston, Huddersfield, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the preceding five weeks from 27·2 to 20·1 per 1000, rose again to 22·8 during the week ending Feb. 27th, but was 0·6 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·6 in Leith and 18·6 in Edinburgh to 25·3 in Paisley and 25·6 in Greenock. The 635 deaths in these towns included 24 which were referred to whooping-cough, 16 to measles, 12 to diarrhœa, 9 to diphtheria, 5 to "fever," 2 to scarlet fever, and not one to small-pox. In all, 68 deaths resulted from these principal zymotic diseases, against 46 and 62 in the preceding two weeks. These 68 deaths were equal to an annual rate of 2·1 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 22 and 15 in the preceding two weeks, rose again last week to 24, of which 14 occurred in Glasgow, 5 in Aberdeen, and 3 in Greenock. The 16 deaths from measles showed a further increase upon recent weekly numbers, and included 14 in Glasgow. The fatal cases of diphtheria, which had been 1 and 8 in the preceding two weeks, further rose last week to 9, of which 4 occurred in Glasgow and 2 in Edinburgh. The 5 deaths referred to different forms of "fever" showed a decline of 5 from the number in the previous week, and included 2 in Glasgow and 2 in Paisley. The deaths referred to diseases of the respiratory organs in these towns, which had been 146 and 154 in the preceding two weeks, further rose last week to 165, and exceeded by 19 the number in the corresponding week of last year. The causes of 66, or more than 10 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·8 and 37·4 per 1000 in the preceding two weeks, further rose to 39·5 during the week ending Feb. 27th. During the first eight weeks of the current quarter the death-rate in the city averaged 39·6 per 1000, against 32·3 in London and 20·1 in Edinburgh. The 265 deaths in Dublin during the week under notice showed an increase of 14 upon the number in the preceding week, and included 8 which were referred to whooping-cough, 7 to "fever," 3 to measles, 2 to scarlet fever, 2 to diarrhœa, and not one either to small-pox or diphtheria. In all, 22 deaths resulted from these principal zymotic diseases, equal to an annual rate of 3·3 per 1000, the zymotic rate for the same period being 2·5 in London and 1·2 in Edinburgh. The fatal cases of whooping-cough, which had been 3 in each of the preceding two weeks, rose to 8 last week. The deaths referred to different forms of "fever," which had been 1 in each of the previous three weeks, rose to 7 last week, and exceeded the number in any week during the current year. The 3 fatal cases of measles and the 2 deaths from scarlet fever corresponded with the numbers recorded in the preceding week. The 265 deaths in Dublin last week included 42 of infants under one year of age, and 84 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a further increase upon the numbers recorded in recent weeks. Three inquest cases and 6 deaths from violence were registered; and 73, or more than a fourth, of the deaths occurred in public institutions. The causes of 32, or 12 per cent., of the deaths in the city last week were not certified.

CALCUTTA AND ITS AMALGAMATED AREA OF SUBURBS.

We gather from the health officer's report that the total number of births registered in Calcutta in October last was 731, giving an annual ratio of 18·8 per 1000, which is rather lower than the average. The total number of deaths during the same month was 1204, against 1041 in the preceding month, showing an annual ratio of 30·9 against 26·7 per 1000 of population. The monthly total exceeds all the corresponding figures of the past decade, and surpasses the decennial mean by 189. There were 185 deaths from cholera, against 82 in the previous month. This number is greater than the corresponding figures of the last ten years. There were no deaths from small-pox during the month under record. The deaths from fevers and bowel complaints were somewhat in excess of the average. There were 49 deaths from tetanus, against 80 in the previous month. Of these, 46 were under one year of age. As regards the local distribution of diseases, the sections of Hastings, Bamun Bustee, and Jorrabagan show the highest death-rates. The mortality of infants under one year of age reckoned on estimated births was 281·6, against 342·9 in the preceeding month, per 1000 per annum. In the amalgamated area of suburbs there were 350 births registered during the month, or in the annual ratio of 19·5 per 1000. The total number of deaths in October was 667, against 603 in the previous month, or in the annual ratio of 37·1, against 33·6 per 1000 of population. Of these deaths there were 61 from cholera, 264 from fevers, 120 from bowel complaints, and 34 from tetanus. There were no deaths from small-pox in the suburbs during the month.

THE SERVICES.

THE ARMY ESTIMATES.

THE Secretary of State for War has followed his accustomed practice in publishing a memorandum relating to the Army Estimates for 1892-93. The memorandum is only intended to summarise and explain a few details of the estimates, and we select from it a few points of interest. The amount asked for in the estimates shows a net increase of £85,900 as compared with last year. The proposed expenditure for 1892-93 is £17,631,300, of which £14,564,100 is for effective and £3,067,200 for non-effective service. The number of men in the Establishment shows no great variation. The Army Reserve is expected to reach during the year the large total of £78,000 men. The report of the Inspector-General of Recruiting shows the physique of the recruits to be satisfactory. The Volunteers show a marked increase in numbers, but the dearth of officers still continues. There is an increase this year upon the Works Vote amounting to £85,400, attributable to the urgent necessity for providing new ranges, and for the further carrying out of sanitary improvements throughout the barrack system of the country.

Surgeon-Colonel A. F. Bradshaw, C.B., has been appointed Principal Medical Officer to Her Majesty's forces in India, vice Surgeon-Major-General Thomson, about to retire.

Surgeon-Colonel A. C. Gaye has been appointed to the officiating medical charge of the Sirhind District, vice Surgeon-Colonel T. N. Hoysted, transferred to the Madras Presidency.

Surgeon-Colonel F. W. Wade has been appointed to the administrative charge of the Allahabad District, Bengal command, vice Surgeon-Colonel T. Walsh, transferred to the Oude and Rohilund District.

Surgeon-Colonel A. Allan has handed over his charge as Principal Medical Officer, North British District, and embarked for Bengal.

ARMY MEDICAL STAFF. — Surgeon-Captain Richard Edward Ricketts Morse, from the Seconded List, to be Surgeon-Captain (dated March 1st, 1892); Surgeon-Captain Norman Macbeth Reid retires from the Service, receiving a gratuity (dated March 2nd, 1892).—The surname of Surgeon-Captain P. J. R. Nunnerley is as now, and not as stated in the *Gazette* of Sept. 1st, 1885.

NAVAL MEDICAL SERVICE. — The following appointment has been made at the Admiralty:—Surgeon Herbert Canton to the *Victory*, additional, for study at the metropolitan hospitals and for Haslar Hospital (dated March 1st, 1892).

Correspondence.

"Audi alteram partem."

THE GRESHAM UNIVERSITY.

To the Editors of THE LANCET.

SIRS,—Permit me to make a slight correction in your excellent leading article on "The New University for London" in THE LANCET of this day. You say that in my "oft-quoted" letter I express the opinion that in the case of the "London diplomates" a clinical examination only would suffice. The words I used were "practical and clinical"—I mean "practical" in its widest sense—in the laboratory rather than in the class-room; in the laboratories of physiology, pathology, forensic medicine, and hygiene; in the dissecting and post-mortem rooms. The "oft-quoted" letter to which you refer, though expressly stated to be unofficial—as much so as this,—has received, most undeservedly, an amount of attention that is rarely bestowed upon official documents, and has been used with more ingenuity than ingenuousness in support of the contention that I advocated a lowering of the degree of M.D. in the new University. It has been attacked by the authorities of the Victoria University, it has been published in the appendix to a petition that has been presented to Parliament, and it has been so unfortunate as to meet with the disapproval of philosophers and scientists who, with little or no experience of medical education and its requirements, are quite prepared to legislate for it by what you truly term "impracticable schemes." And lastly, it has been used by writers in the daily press to make "political capital" against the Charter.

Those self-constituted champions of a "high standard," the authorities of the Victoria University and my friends the philosophers, persist in accusing me of seeking to lower the standard of education in respect to the medical degree of the new University. I most emphatically deny ever having had or having expressed such an intention. The charge is absolutely untrue. The "oft-quoted" letter on which it is founded had no reference whatever to the curriculum of the student qualifying for a degree in the University. It referred solely to the question of the admissibility of the "London diplomates" to examination for the M.D. degree, that examination being a final one from which all "preliminary science" must necessarily be excluded. What I did say was that a good qualification might be taken in the case of these diplomates as equivalent to the M.B, and that such a qualification was the M.R.C.S. and L.R.C.P., and I contend that this combined qualification is equivalent to the M.B. of any university in the kingdom, with the single exception of that of London, and possibly that of the Victoria University, of the relative value of which I regret to have to confess my ignorance; and that the London diplomates suffer under a real and substantial grievance in its not being so recognised.

It is absurd to speak of a "standard" in scientific or medical examinations qualifying for degrees. There is no such thing. Every university and medical college has its own "standard," determined by its own governing body, as will be the case in the Gresham University should its Charter—happily for medical education—be granted. Can it be pretended that the "standard" is the same in the University of London and that of St. Andrews, that of Cambridge and that of Glasgow?—in the Royal College of Surgeons of England and in that of Edinburgh, in the Royal College of Physicians of London and the College of Physicians and Surgeons of Glasgow? There is not only no uniformity in this respect amongst the different degree-giving and licensing bodies in the kingdom, but the standard will vary in the same institution at different times, according to the views of its Senate or Council for the time being. This is a question of statute or by-law, and not of charter. Which, then, of these "standards" am I accused of wishing to lower? That of London or that of St. Andrews?—that of Cambridge or that of Glasgow? But perhaps the true standard of excellence is to be found at Manchester, and there only.

I am, Sirs, yours very obediently,

Eastbourne, Feb. 27th, 1892. JOHN ERIC ERICHSEN.

To the Editors of THE LANCET.

SIRS,—In your notice of my little volume in your leading article in last issue you speak of me as advocating the "absorption of the governing bodies of the two teaching colleges and the ten medical schools into the Senate of the University." If you will re-examine p. 116 of my book you will find that what I say is: "That after the first constitution of the faculties no further appointment to College posts shall, *ipso facto*, make the holder a member of the faculties of the new university *in arts, science, or law*, but that the university shall itself nominate to its own faculties." This expressly excludes the Faculty of Medicine, which I am quite aware needs peculiar dealing with. I think this clears off the objections you raise as to the absorption of the medical schools. I am quite certain that no high standard will be maintained on the science and arts side of the proposed university unless the appointments are made by the governing body of the University itself. The powers of extra-collegiate lecturing must be extended if the University is not to present the absurd spectacle of being called "Gresham," but excluding all teaching done at Gresham College from its graduation courses. The Charter, as it stands, needs amending in the direction of wider powers of extra-collegiate teaching just as much for the sake of the highest as for the lower forms of work. It is the former which Sir Thomas Gresham originally intended to assist by his foundation.

My modifications (3) and (4) are especially intended to cut the ground from under the feet of far more serious opponents of the Charter than myself. You possibly, Sirs, have no idea of the parliamentary strength of the "Extension" and "External Medical Schools" oppositions. But unless these opponents are met by modifications in the House, and those I have suggested are the least feasible, I do not think the Charter has any chance of surviving. I believe that the only way for those who wish to see a Teaching University in London is to work for the modification of the Charter in such a manner as will really strengthen it, while disabling opposition. I have good ground for thinking that in pressing the Charter as it stands, you are destroying all hope of carrying it. So far as medicine is concerned, my modification (3) is the only one that touches it, and on your own showing this is practically accepted by the London members of the profession. If you do not want Manchester, Leeds, Liverpool, Bristol, and Birmingham to vote solidly against the Charter, you must be prepared to accept some modification of the kind I have suggested.

It is, Sirs, perfectly open to Parliament to petition that the Charter be *suspended* until modified, and I believe the only alternative to absolute rejection is suspension. If this be so, surely an influential journal like THE LANCET should work for the latter alternative.

I am, Sirs, your obedient servant,

University College, March 3rd, 1892. KARL PEARSON.

*** We did not say that Professor Pearson advocated "the absorption of the governing bodies of the two teaching Colleges and the ten medical schools into the Senate of the University," but that his second provision could only mean this. No one conversant with the composition of the governing bodies of the medical schools could have suggested such an obviously impracticable proposal. His method, which again, is an impossible one, of dealing with the medical problem is stated in his appendix (p. 133). Professor Pearson has hitherto urged, without sufficient foundation, that the medical faculty intended to lower medical degrees. There are not, so far as we can see, any stronger grounds for his assertion that the professors in the two Colleges will not "maintain a high standard in arts and science." This seems to us most unjust to his colleagues in those faculties. We still believe that the Charter must be accepted or rejected as it stands.—ED. L.

POST-MORTEM APPEARANCES OF THE BRAIN OF INFLUENZA PATIENTS.

To the Editors of THE LANCET.

SIRS,—Dr. Goodall's account of the post-mortem appearances which he has found in fatal cases of influenza at the West Riding Asylum forms indeed a singular contrast to the results which I had mentioned in a previous letter as obtained by Helweg of Aarhus. I think it will be interesting to your readers, in connexion with this, to be informed of the results of twelve necropsies of gripped patients made by Maillart[1] in the Cantonal Hospital of Geneva. In the first case there was great hyperæmia in the right hemisphere of the cerebellum, with hæmorrhagic spots, and complete softening of the medullary matter. In the second case there was found copious hæmorrhage at the base of the brain, proceeding from an aneurysm of the basilar artery, there being liquid blood in the right lateral ventricle, and granular ependymitis. In the third case the dura mater was completely adherent to the skull, and the pia mater thickened and strongly congested. In the fourth case there was acute non-suppurating lepto-meningitis; the pia mater showed strong œdematous infiltration at the convexity as well as at the base, the vessels being very turgescent. In the next three cases, where the patients, being previously consumptive, had died of rapid progress of the tuberculosis subsequent to the attack of grip, the condition of the brain is not mentioned. In the eighth case there was hæmorrhagic pachymeningitis, chiefly in the middle *fossæ*. In the ninth case there was general subarachnoid œdema. In the tenth case, which was that of a tubercular and alcoholised person, there was strong subarachnoid œdema. The left Sylvian artery was surrounded by a loose non-transparent tissue, and showed numerous miliary tubercles in its tract. On the right side the same lesions were found, although not so pronounced. There were a few miliary tubercles on the bloodvessels of the anterior surface of the pons and internal hydrocephalus. In the eleventh case slight subarachnoid œdema and lepto-meningitis with hyperæmia were discovered. Finally, in the twelfth case, the pia mater was found covered with a thick layer of greenish, thick, and ropy pus on its whole surface, at the base as well as at the convexity, and the membrane was strongly œdematous. The lateral ventricles were likewise found to be filled with the same kind of pus. Everyone must admit that such a series of records is very significant, and cannot be simply due to coincidence, more especially when it is remembered that the cases were not of inmates of an asylum, but of persons indiscriminately admitted for severe forms of grip into a general hospital.

I am, Sirs, yours faithfully,

Harley-street, Feb. 29th, 1892. JULIUS ALTHAUS, M.D.

[1] Étude Clinique sur la Grippe pandémique d'après les Observations recueillies à l'Hôpital Cantonal de Genève pendant l'Epidémie de 1889-90. Genève, 1891.

RETRO-PHARYNGEAL ABSCESS.

To the Editors of THE LANCET.

SIRS,—I have read Mr. Pollard's paper in THE LANCET of Feb. 6th on Retro-pharyngeal Abscess with great interest. About ten weeks ago an infant aged four months was brought to me suffering from one. The history given was the following: The child had always been ailing, and from birth had difficulty in breathing, especially when asleep. On examination the fauces were congested, the tongue was furred, and the child presented all the symptoms of croup, for which I at first treated it. As the dyspnœa continued to increase I examined the pharynx, and found an elastic swelling behind the right tonsil, and extending laterally beyond the middle line and below, reaching to the upper part of the larynx. I opened the swelling through the posterior wall of the pharynx, inverted the child, and washed out the mouth. There was instantaneous relief. Three days after this I was hurriedly summoned to the child, as it was said to be dying. I found that the abscess cavity had refilled, and the dyspnœa was intense. A free opening was made into the swelling, and about a tablespoonful of fetid pus was expelled. The mouth was washed out twice daily, the child being inverted. There has been no return of the abscess, and the child is now in good health. I am of opinion that retro-pharyngeal abscess in infants is sometimes of syphilitic origin, and is not such a rare affection as Mr. Pollard imagines. Probably cases occur which are mistaken for croup, and treated as such, the error never being rectified.—I am, Sirs, yours faithfully,

Stamford-hill, N., Feb. 21st, 1892. DANIEL MOWAT.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Hospital for Diseases of the Chest.

THE annual meeting of the Northern Counties Hospital for Consumption and Diseases of the Chest at Newcastle has been held. The Mayor presided. The total number of patients treated has been 1084. The financial statement was satisfactory, showing a balance in the hands of the treasurer. Reference is made in the report to Koch's treatment for consumption, which was carried out last year at the hospital. It says that a special nurse was engaged, and careful notes were made of the course of the disease in those patients who were subjected to this treatment, who had been selected with a view of giving it the best possible chance of success. In this the medical staff had the coöperation of Dr. George Murray, through whom the supply of tuberculin had been received, and who brought it directly from Koch at Berlin, so that there could be no doubt as to its genuineness. The result of these and other experiments is that the opinion formed by the medical staff is unfavourable to its use in its present form, and that, while not denying that it may be of some service in a few cases, they consider that it was not of much practical value in the cases which came under treatment at the hospital.

Gateshead Dispensary and Children's Hospital.

The report of the Gateshead Dispensary, presented at the meeting held last week under the presidency of the Mayor, is a record of an enormous amount of work, as will be seen from the following figures: Patients treated by letter, 3537; casuals, including 249 accidents and 425 dental cases, 11,281. Thanks were accorded to the Hospital Sunday Fund and the Gateshead Dispensary ball committee, and the honorary medical staff and other officers were congratulated on the successful working of the charity. The Children's Hospital at Gateshead has also held its annual meeting. There had been a slight increase of patients, 82 in-patients as against 74 in the previous year; whilst 765 out-patients had been attended to. The financial statement was very satisfactory, the year closing with £153 in the hands of the treasurer on current account. Mr. William Rowland had given £300, and the late Dr. Benjamin Barkus, formerly of Gateshead, late of Newcastle, had bequeathed £300 to the hospital.

Ambulance Work in the North.

At Seaham Harbour Surgeon-Major Gibbon has commenced a course of ambulance lectures, with lantern illustrations by his son, Surgeon Fred. W. Gibbon, of the Tyne Dock Volunteer Engineers. There was a large attendance at this lecture, including most of the police force of the district. At Wooley also a public meeting, in connexion with the ambulance class has been held, and Surgeon-Major Hutton delivered a lecture. At this meeting a presentation was made to Dr. Dey (who had successfully instructed the class during the winter) of a handsome marble timepiece, with appropriate inscription, from the class. Mr. G. P. Hughes, High Sheriff of Northumberland, made the presentation.

Epidemic of Diphtheria in the Houghton-le-Spring District.

There has been a serious epidemic of diphtheria at Newbottle, in the Houghton-le-Spring rural sanitary district, and it has been under consideration to destroy all the books at the schools, which have been closed. Such destruction of books would mean a loss of about £100. Another suggestion is to disinfect them, and a new machine has come down from London which, although it weighs about one ton and a half, can be moved about from school to school to disinfect the books.

North-Eastern Convalescent Home.

The second meeting of the North-Eastern Convalescent Home has been held. This institution is for the benefit of the working classes of the friendly societies of the north-

Digitized by Google

eastern counties, and is supported and managed by themselves. It was shown that eighty-one patients had been received during the year, the majority being from Sunderland and other parts of the county of Durham It was stated that the new home at Grange over-Sands would be opened on March 3rd.

"Coals to Newcastle."

"Carrying coals to Newcastle" used to be a saying expressing the very superfluity of useless labour. It appears now that from some cause coals can be bought cheaper at Alexandria than they can just above their native mines. It is not so, however, as to gas, the net price of which is now under 1*s.* 8*d.* per 1000 ft. Our gas, however, as a light, is capable of considerable improvement, and our fellow-citizen, Mr. S. Macaulay, did good service at a meeting the other day by pointing out how our gas could be improved as an illuminant by a mixture with hydro-oxygen gas. It was manufactured from crude oils, which were refined during the process of manufacture by this gas. Mr. Macaulay said the fifteen-candle coal gas could be increased to twenty-candle at a cost of 3*d*, while the additional cost of coal gas to give the same power would be 8*d.*

Newcastle-upon-Tyne, March 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh University Court and the Universities' Commission.

AT the request of the Commissioners, the University Court has submitted a "Memorandum on the Financial Requirements of the University of Edinburgh." The document embodies reports from the several faculties and from the Science Degree Committee received through the Senators. The following are some of the memoranda which bear upon medicine, and are sufficient indication of the views of the Court. No new chair is asked for by the Faculty of Medicine, but the Faculty of Law suggest that if a claim of Public Health be formed, an adequate endowment should be provided for the chair of Medical Jurisprudence. Additional claims are made by the Faculty of Medicine on behalf of lectureships, as follows—viz., £50 for each of the following: Clinical Medicine, Fevers, Laryngology, Rhinology and Otology, Ophthalmology, Mental Diseases, and Diseases of Children; claims by the Science Degrees Committee include £150 each for Plant Pathology, Plant Physiology, Bacteriology and Embryology, and of £200 for Veterinary Hygiene. The several faculties as well as the Science Degree Committee suggest the institution of a number of new lectureships as the mode in which the teaching staff should be increased, and the Court agree generally with this. The Faculty of Medicine think that adjunct lectureships would be instituted within several of the professorial departments by conjoining lectureships with the duties of some of the assistants. Further additional claims are made for assistantships in the Faculty of Medicine, the present sum received being £1150, and the new claim amounting to £3410. As explaining this claim it is submitted that the professors have from time to time appointed such additional assistants as the increase in the number of students rendered necessary, and either paid altogether or supplemented the stipends out of their class fees. The same Faculty advance claims for laboratory and class expenses; at present they are allowed £381, and they claim £1909 The Faculty further suggest that, owing to the great educational value of research work, and its importance as a means of maintaining and increasing the success and reputation of the University, the Commissioners should establish a Research Fund, out of which grants might be made to the different departments in which original work is being pursued for the purpose of defraying the expenses incurred. It is also considered important to state that many of the professors have provided, from their private resources, apparatus and other appliances for improving and illustrating their teaching. The Faculty consider, if the method of payment of the professors be materially altered, that this outlay should be returned, and the articles secured for the University. From the foregoing it will be seen how much and how little have come from the Senatus and the University Court in the way of suggestion either as to improvement or advance in teaching and other matters in the University. It was the conviction of this which was forced upon those who are not of the thirteen professors that it was necessary to show what was required for the advanced and advancing scientific teaching and investigation in the medical sciences, and it was from them that the Reform Association sprang

Professor Ferrier in Edinburgh.

Professor Ferrier, as Cameron Prizeman of the Edinburgh University, delivered a lecture in the Oddfellows' Hall on "Cerebral Localisation in relation to Therapeutics." Professor Fraser, in the absence of the principal, occupied the chair. The hall was crowded by students, and the lecturer was listened to attentively and frequently applauded. Later he was the guest of the evening at the annual dinner of the Royal Medical Society.

The Edinburgh New Town Dispensary.

The annual meeting of this valuable charity was held last week. During the year 9054 cases had been attended, of which 1925 had been visited at their own homes. The financial condition was satisfactory.

Health of Edinburgh.

The mortality last week was 85, and the death-rate 17 per 1000. Diseases of the chest accounted for 40 deaths, and zymotic diseases for 7, of which 2 were due to diphtheria and 2 to measles. The intimations for the week were: Typhoid fever, 2; diphtheria, 3; scarlatina, 16; and measles, 79.

Royal Society of Edinburgh.

At a special meeting of this Society, held on Monday, Professor Cossar Ewart made a communication on "The Cranial Nerves of Man and Salachians."

Association for the Reform of Medical Education.

Owing to Dr. Berry Haycraft having resigned the co-secretaryship of this Association, Mr. Charles W. Cathcart has been appointed Dr. Berry Hart's co-secretary.

The Physiological Department and Dr. Haycraft.

Dr. Haycraft's connexion with this department ends with the winter session. Dr. Haycraft has not resigned, and, as he gave up a professorship elsewhere to come to the rescue of the University at a well-known crisis, much sympathy is felt for him.

Special subscriptions to the amount of £7000 have been raised for the purpose of increasing the Paisley Infirmary buildings.

It is stated that Lady Jane Dundas has announced her intention of giving £10,000 to the Edinburgh Hospital for Sick Children as a memorial of her sister, Lady Margaret Charteris, who died a few weeks ago.

Mr. John Phillips, M.A., M.D. Cantab., M.R.C.P., has been appointed Examiner in Midwifery to the Glasgow University.

March 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Banquet at the Royal College of Surgeons.

MR. H. GRAY CROLY, President, has sent out cards for a banquet to be held in the College on Monday evening, the 14th inst., in celebration of the first biennial presidency. His Excellency the Lord-Lieutenant and a distinguished company will be present.

Green street Court house, Dublin.

An eminent sanitary engineer has certified that this court house is unfit for human occupation, and the legal business has been transferred to the Four Courts until a new courthouse has been erected.

Proposed Hospital for Consumption, Dublin.

About £5700 has already been subscribed towards the building fund, which is over one-half of the sum required for successfully starting the hospital. The executive committee are taking steps to establish local committees throughout the country, and it is confidently expected that sufficient money will be subscribed to enable the building operations to be commenced early in the spring. I do not think there will be much difficulty in collecting the required amount for building the hospital—say, about £15,000,—but

Digitized by Google

it is possible the annual cost of maintenance—some £5000—may not be so easily obtained.

Zymotic Diseases in Dublin.

An impression has become rather prevalent of late that the mortality from zymotic diseases in Dublin is unprecedentedly high, but Sir C. Cameron has shown by statistics that the death-rate from contagious diseases is very much less than in the twenty-eight largest towns of England. For example, the zymotic death-rate of Dublin in 1887 was 4·5 per 1000, in 1888 it fell to 2·8, in 1889 to 2·3, in 1890 to 2, and last year, notwithstanding the prevalence of typhoid fever, to 1·6, or about one-half the rate in London.

Census for the Province of Leinster.

It appears from a recent return of the Census Commissioners that the number of inhabitants in this province by the last census was 1,187,760, or 7·1 per cent. less than in 1881. While in 1881 20·3 per cent. of the population were illiterate, in 1891 the percentage had fallen to 15·4. The births registered during the ten years ending March 31st, 1891, were 291,151, and the deaths 254,834, showing a natural increase of 36,317 in the population. The decrease in the population as shown by the census returns was 91,229, as compared with the previous return, a disparity in the results to be accounted for to some extent by the fact that no record of immigrants or of migration from one part of Ireland to another is obtainable.

The Royal Hospital, Belfast.

At the quarterly meeting of the supporters of the Royal Hospital, held on Feb. 22nd, a very satisfactory report of the financial condition of the institution was submitted. At the end of the last quarter the hospital was in debt £3015 15*s.* 4*d.* This is now paid, and a balance is in the hands of the treasurer. The Centenary Bazaar realised £3573 14*s.* 6*d.* Since the beginning of the last financial year (September) £1842 19*s.* has been received, this being an increase over the corresponding period of last year. During the past quarter there were 719 intern and 4516 extern patients.

Queen's College, Belfast.

Some time since a lectureship on pathology was established at Queen's College, and out of several candidates the Council, with the sanction of the Lord Lieutenant, have unanimously appointed Dr. W. H. Barrett, who in 1886 succeeded Dr. Sims Woodhead as senior assistant to Professor Greenfield of Edinburgh. Dr. Barrett has also been pathologist in the Edinburgh Royal Infirmary. Dr. Barrett will enter on his new duties on May 1st, and will conduct two classes—one of systematic and one of practical pathology, for which, as for laboratory and research work, rooms are in process of preparation in the medical buildings of the College.

The New Consumption Hospital, Belfast.

At an "at home" given by Mrs. Purdon (widow of the late Dr. J. H. Purdon) the plans were shown of this new institution, which is to be erected at Ballynafeigh. At the outset it has been arranged to have accommodation for twenty-four intern cases, and already a sum of about £6000 has been subscribed towards its erection. Considering the immense death-rate from chest diseases, and especially from phthisis, in Belfast, this new hospital will meet a great want.

Health of Belfast.

The first annual report of Dr. Whitaker, medical officer of health for Belfast, has been presented, and from it I learn that the Registrar-General in Belfast estimated the population of the urban districts too low, and hence during the last decade the death-rate was considerably over-estimated. In 1890 the death-rate was 29·5 per 1000 as returned by the Registrar-General, while the proper return was 26·7. During the fifty-two weeks ending Jan. 2nd, 1892, there were reported 340 cases of zymotic diseases, while in 1890 there where 614. The births for the year 1891 were 8650, the deaths 6537, the difference being a natural increase of population of 2113. Dr. Whitaker calculates the death-rate of Belfast for 1891 as 25·5, and the birth-rate as 33·7 per 1000, which is much in excess of the average of other large towns. Of the 6537 deaths registered during the past year 1017 were attributable to phthisis, whilst 1734 were due to disease of the respiratory organs. Dr. Whitaker refers to the following as some of the causes of the high death-rate of Belfast: 1. The dampness of the soil and air. 2 Flooding of the houses in some low-lying districts. 3. The existing system of privy and ashpit. Some 40 per cent. of the houses in the city have this vicious system. 4. The stagnation of the sewers and absence of flushing or ventilation. A great amount of low form of disease, Dr. Whitaker thinks, is caused in this manner. A ventilating shaft is now being tried as an experiment on one of the main sewers. 5. Unhealthy occupations principally affecting the respiratory organs. The dust of the flax, the staple trade, is a serious cause of bronchitis and phthisis. The dampness of the soil on which Belfast is built, combined with the very frequently moist atmosphere and the unhealthy occupation of many of the factory workers, predispose to chest diseases. 6. Foundations of too many of the houses are built on ground filled not only with mud, but sometimes with most objectionable material. During the past year many improvements have been made in the sanitary arrangements of the city of Belfast; but there is still room for improvement in many other matters, which Dr. Whitaker promises to bring from time to time before the Public Health Committee. A step in the right direction has been taken in the decision to clear out periodically (free of charge) all the ashpits in the city.

Mr. McGrath has been appointed joint secretary to the Royal University of Ireland in the vacancy created by the decease of Mr. Dunne.

In addition to the ordinary degrees conferred by the University of Dublin for Hilary Term on Tuesday, the 2nd inst., the honorary degree of Doctor of Laws was conferred on the Bishop of Derry and on the Lord Mayor of Dublin.

March 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Polyuria in Sciatica.

IN October last MM. Debove and Rémond called attention to the frequency of polyuria in cases of sciatica, and these observers believed this phenomenon to be attributable to an increase of arterial tension, consecutive to morbid excitation of the sciatic nerve. M. Huchard has since studied the subject, and he now announces[1] that, of ten such patients kept under observation, in the majority the quantity of urine excreted was rather diminished than increased. In three instances the polyuria noted was proved to be due to generalised arterio-sclerosis or to commencing renal sclerosis. M. Huchard agrees, then, with M. Lépine in considering polyuria rare in sciatics, and, going still further, deems the opposite condition—viz., oliguria—to be more frequently met with in very painful sciatica. Whenever polyuria is present he ascribes it, in the majority of cases, to a concomitant or intercurrent malady. M. Huchard appears to agree with the conclusions formulated some time ago by M. Hugonnard, a pupil of M. Lépine—viz., that moderate or strong stimuli brought to bear on the sciatic nerve diminish or even totally arrest the secretion of urine, while slight stimuli have the opposite effect of increasing such secretion.

Mammary Abscess in the Newborn.

The mammary engorgement observed in the majority of the newborn during the first few days of extra-uterine existence is now known to be a physiological phenomenon, accompanied by a milky secretion, which, after having lasted two or three weeks, generally subsides spontaneously. Recent analyses have proved that the liquid secreted is analogous to, if not absolutely identical with, woman's milk. In certain rare instances the swelling of the gland may proceed to suppuration, which, in the case of a female child, cannot but be regarded as an unfortunate incident. M. Comby[2] warns against the usual practice of artificially emptying the lacteal ducts in such cases, pointing out the double danger of destroying the gland altogether, or of inducing what it is meant to prevent—suppuration—by introducing through the medium of unclean fingers germs into the inflamed tissue. M. Comby recommends the covering of the tumefied part with emplâtre de Vigo (mercurial plaster), or, if that preparation prove too irritating, with the emplâtre rouge (emplastrum roborans).

Wanted, a Doctor!

It is not only in England that the lamentable wave of immigration flows so steadily towards the towns, to the great detriment of the rural districts and of the country in general. This economic phenomenon is also a feature in French life, and in no class of society is it more marked than amongst doctors. The towns tend to be overstocked with them, whilst the country is insufficiently supplied with properly qualified men. The institution of the inferior diploma of *officier de santé*—a diploma now condemned by the new Medical Bill soon to become law—was designed to meet this difficulty; but the remedy has, by universal consent, proved inefficacious. The very moderate fees paid in country districts are probably responsible in the main for the sparseness of the medical population in such places. The following pathetic appeal for a medical man, which I extract from a Paris medical journal, is characteristic, and is confirmatory of the truth of the preceding remarks: "Vacances médicales.—Toute une population, d'environ 6000 habitants, répartis dans un rayon de 4 kilom. autour de la résidence, demande ardemment un médecin pour remplacer celui qui exerçait autrefois dans la localité. Il s'agit d'un pays admirablement situé, à 6 lieues de Rouen, dans lequel les visites aux indigents sont payées 2 fr. par le Bureau de Bienfaisance. Cette position conviendrait merveilleusement à un jeune médecin instruit et de parfaite honorabilité." Can we wonder that the French peasant falls so easy a prey to the enterprsing charlatan?

Paris, March 2nd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Electrical Executions made Public.

THE law changing the method of execution of criminals in the State of New York from hanging to electricity required that the execution should be in the State prisons, and that only a few officials should be present. These officials were forbidden making any public statement of the details of the execution, and thus the newspapers were deprived of the opportunity of filling their columns with the over-wrought accounts of the sickening scenes which so interest the mass of readers. The reporters hovered around the prisons at each execution, but they learned so little that it was impossible for them to make an exciting story of the event. Not to be baffled in their efforts to utilise the exciting and entertaining scenes of an execution by electricity, the newspaper men have succeeded in having the law so amended that reporters are now admitted to the prison and allowed to describe with pen and photograph all of the revolting details. An execution has just occurred, and as a result of the new law the papers are filled with the most sensational statements and pictures which could be devised. The victim is fastened in the chair, the priest stands with prayer book in hand on one side, the chief executioner, a physician, on the other; the reporters, with pencils or watches in hand, stand near. The chief executioner explains: "We purpose to-day to vary the method employed here by making the contact through the hands instead of from the top of the head to the leg, as has been the custom heretofore. The hands will be placed in a salt solution in the two cells, and the current will pass directly through the chest. While we have many assurances that this method will be successful, we have retained the electrodes at the head and leg, so that if it fails to be satisfactory, a simple turning of the switch will turn the current from the head downwards as before." He added that this was an experiment. Everything being in readiness, the report states that the victim's voice, which had been low and hardly audible, rang out loud, and, with a wailing, struggling sound, dying away with the last choking utterance of a man in dreadful fright. "Let her go!" These were his last words; the current was turned on; the murderer bounded up with a powerful convulsive movement as if he would burst the bands; his chest arched out, and the strap which held it creaked with the strain; the face contracted on one side, as if expressing ineffable pain; the legs tugged at the straps, and one foot was drawn up sideways; the lips slowly opened and disclosed the teeth tightly clenched. At the end of fifty seconds the current was turned off, when the victim's chest slowly collapsed, with a wheezing, coughing, gasping sound from his lips, and saliva was blown from his mouth and ran down the chin. "Turn it on the other way," said the physician, when the body straightened up again with a jerk, the legs struggled in the straps, the chest was thrown out more powerfully than before; steam began to arise from the electrodes. In thirty-eight seconds the current was turned off, and the man pronounced dead. "I think every physician here," said the executioner, "will agree with me that the subject was dead, so far as his conscious being is concerned, the instant the first shock reached him. It is now apparent that he is dead muscularly also—that is, he is dead as an animal. If there is any physician who does not agree with this statement I wish he would say so." One of the physicians present said, "I agree that the man became unconscious at the first shock, but I do not agree with the test of it." Thus closed another act in the drama of "electrocution," and the public has been made familiar with the revolting details. The new method has not gained in popularity by this exposure.

Russian Hebrew Immigrants Spreading Typhus Fever.

New York is threatened with an epidemic of typhus fever through Russian Hebrew immigrants. Seventy-six cases have been found during the last two or three days in the lodging-houses provided for these immigrants by the United Hebrew Charities Association. These immigrants landed on Jan. 10th form a vessel from Naples and Marseilles. It appears that these typhus fever patients were only a small part of a shipload of Russians and Italians who had sailed from Marseilles about six weeks ago. They are part of a group of 1556 Russian and Polish Hebrews who sailed from Odessa to Constantinople four months since. They were suffering from the hardships of famine. The managers of the Baron Hirsch fund were going to send them to Palestine, but their condition was so distressing that the Sultan would not allow them to enter. Those who were too sick and exhausted to travel were left at Constantinople; others were sent to Argentine, and some to Marseilles to be shipped to the United States. Many were sent ashore at Napoli suffering from typhus fever, and 267 embarked for this country with 450 Italians. The health authorities are searching the city for these immigrants, and all the sick are immediately removed to the hospitals for infectious diseases on North Brothers' Island. The infected clothing is destroyed, rooms are cleansed and disinfected, and a constant watch is established upon all exposed persons.

The Public Health of Chicago.

Attention has lately been drawn to the continued high death-rate of the city of Chicago from typhoid fever. More importance is attached to this fact in view of the approaching World's Fair to be held in that city. A recent writer states that the statistics show that typhoid fever has materially increased in Chicago since 1880, and that within the last two years it has risen to an extraordinary height. During the year just ended there were 1977 deaths from typhoid fever, giving the prodigious death-rate for this disease of 16·64 per 10,000 of population, and a percentage of all deaths of 7·19. The cause of this remarkable prevalence of typhoid fever is not considered, but the paper quotes a significant statement of a former health officer of that city, "that the stream of filth coming through the city is a constant menace to the health of the citizens." At a late meeting of the Illinois State Board of Health a resolution was passed appointing Dr. John H. Rauch as a Special Commissioner to investigate the charge that Chicago is suffering from an epidemic of typhoid fever due to a polluted water-supply; and, in view of the widespread publicity of the said charges, and their probably damaging influence upon the World's Columbian Exposition, that the utmost expedition, consistent with thorough investigation, be urged.

Feb. 13th.

Obituary.

EDMUND SPARSHALL WILLETT, M.D., M.R.C.P.

WE regret to record the death, at the age of sixty-four, of Dr. Willett, part proprietor of Wyke House, the well-known private asylum near Brentford. Dr. Willett studied at Guy's Hospital and the Medical School at Bristol, became qualified in 1850, and a year later took the M.D. degree at

Digitized by Google

St. Andrews. At the outbreak of the Crimean War Dr. Willett joined the Medical Staff of the army, and was for some time attached to the 55th Regiment. At the end of the year 1855 he embarked with his regiment for the Crimea, but, falling ill at Malta with fever, he was invalided home, and thus his military career was cut short. After leaving the army Dr. Willett devoted himself to the subject of lunacy, and in 1856 he became the resident proprietor of Wyke House, his connexion with which was only severed by death, which took place on Feb. 20th at Gunnersbury House, whither he removed a few months since, leaving the management of the asylum to his partner, Dr. Murchison.

Dr. Willett was well known and very widely respected in his neighbourhood. He was a gentleman of the best English type, kind, generous, and hospitable. He had been a magistrate for the county of Middlesex for some years, and when the Local Government Act came into force the County Council of Middlesex elected him one of its aldermen. No private asylum stood higher in public estimation than that over which Dr. Willett presided for so many years, and it was well known that his patients were treated with all that generous consideration which hospitable Englishmen are accustomed to show towards their private guests. Dr. Willett was an ardent sportsman, and no one was more popular than he in the hunting field and at the covert side. As a magistrate he knew well how to temper justice with mercy, and his poorer neighbours all found in him a generous friend, ever ready to help them with money and good counsel. Dr. Willett's loss will be very seriously felt throughout his division of the county, for few men were more public spirited, and none more honest or outspoken in the discharge of duty.

ROYAL COLLEGE OF PHYSICIANS.

A COMITIA of the College was held on the 3rd inst., the President, Sir A. Clark, Bart., in the chair.

A communication was read from Sir Dighton Probyn, conveying the thanks of the Prince and Princess of Wales for the sympathy expressed by the College in their recent bereavement.

A communication was read from the College Solicitors together with a statement of claim in the case of the Royal College of Physicians *v.* the General Medical Council.

A report of the delegates appointed by the Royal Colleges to consider a letter from the Secretary for War, in reference to the examinations for admission to the Medical Department of the Army, was read and adopted. It recommends the constitution of a joint committee which should appoint examiners from time to time.

A report from the committee of management respecting the financial arrangements for the five years' curriculum was adopted, and likewise one containing synopses of the examinations in Chemistry, Practical Chemistry, and Elementary Biology.

THE PROPOSED GRESHAM UNIVERSITY.

A DEPUTATION consisting of representatives of various educational bodies, provincial and metropolitan, waited upon Lord Salisbury at the Foreign Office on Thursday, at three o'clock, to lay before him the reasons why, in their opinion, the Charter of the new University, now before Parliament, should be remitted to the Royal Commission for reconsideration.

Lord SPENCER, the Chancellor of the Victoria University, introduced the deputation, stating in a few words the grounds upon which he objected to the Charter, as at present framed, being granted. Principal Rendall, the Vice-Chancellor of the University, however, would place the details before his lordship.

Principal RENDALL said their objections rested substantially upon the ground that in their opinion the power of conferring degrees should be entrusted only to a University with faculties in arts and science as well as in medicine. The specific grounds of objection were the excessive prominence and undue ascendancy given to the medical faculty in the constitution of the proposed University. The principle of the Charter had really been to conciliate and consolidate the whole of the medical opinion in London, and to confederate all the medical schools in the metropolis, great and small, and whether perfectly or imperfectly equipped for the teaching of science, in order to secure the granting of this Charter. Special provisions had been introduced to give representation to the Royal Colleges and the Apothecaries' Society. A University so constituted was without parallel among the Universities of Great Britain. The degree-giving power had never been entrusted to any purely, or even to any mainly, medical body. Owing to the conditions of the profession, to its restrictions, and to the high pecuniary value attached to University degrees, that power had hitherto been very carefully safeguarded. The Victoria University was a good instance of that. Ten out of the twelve colleges possessed no means of teaching science beyond what was correlated to the science of medicine, and, of these ten, one was destitute of even the means of providing the slender modicum of science required for the University degree in Medicine. On these and other grounds he hoped that Her Majesty would withhold approval from the Draft Charter until it had been reconsidered in accordance with the recommendations of the Royal Commission.

Mr. JOSEPH CHAMBERLAIN, M.P., said he had been asked to appear on behalf of Mason's and Queen's Colleges of Birmingham, of the medical schools of Bristol, Leeds, Liverpool, Sheffield, and the medical department of Owens College, Manchester, and the representation was supported by the Members of Parliament of the respective districts. These bodies, he said, approved of the policy of creating a teaching university in London, but they objected very strongly to the Charter as it at present stood, as it would lead to the degradation of the medical degree in Great Britain, and seriously injure the prosperity of provincial colleges. He alluded especially to a recent speech of Sir George Young and a letter written and subsequently published by Professor Erichsen, suggesting that the Council of the new University would allow persons who possessed an ordinary qualification in medicine to obtain the degree on passing the final examination of the proposed University. It would undoubtedly take away many students from the provincial colleges, which stood higher than some of the colleges which were proposed to be made constituent colleges of the new University. It would be a strange anomaly if students could actually get a higher degree by attending institutions where they would get a lower education. These were the grounds on which the provincial colleges hoped that Her Majesty's Government would see fit to withdraw the Charter and give its provisions further consideration.

Lord DERBY appeared as Chancellor of the London University, though not in any official capacity, and pointed out some of the objections urged by that body against the Charter

Mr. E. H. BUSK went in detail over much the same ground.

Other speakers, among whom was Mr. Bartley, M.P., representing various metropolitan bodies, laid their views before his lordship.

Lord RIPON, who represented the London Society for the Extension of University Teaching, gave an account of the foundation of this movement sixteen years ago by Mr. Goschen and himself. Now over 13,000 persons attended courses in the metropolitan districts, the most of whom were very anxious to obtain the highest education in the country, but had no means of study except that afforded by evening classes, and it was highly desirable to afford them opportunity of gratifying their laudable ambition. There was a certain number of these students who would be fully able to pass the examination for a degree. All that they asked in regard to this Charter was that power should be given to the new University to recognise the University extension system in its fullest sense, and that they should be able, if they thought fit, to give degrees to such students as proved themselves worthy of them.

Lord SALISBURY thanked the deputation for the important matter which had been placed before him with regard to the Charter. He would not venture to express either assent to or dissent from what he had heard, nor would he discuss it, because he was not in a position to criticise the statements of those who had more knowledge in this matter

Digitized by Google

than himself, and because the time left at his disposal was now very short. While thanking them for what they had laid before him, he promised to give it most careful consideration, so far as consideration was required by the Government. He wished to impress upon the deputation one point of great importance—that, so far as they were concerned, this proceeding was somewhat late. He imagined it should have been taken while the matter was still before the Privy Council. Several times in the course of the proceedings it had been mentioned that they should withdraw or revoke the Charter. He spoke with submission, but he very much doubted whether they had the power to do so. The Charter was now before Parliament, and it lay exclusively with the two Houses to say whether the Charter shall be valid or cease to be valid. If it became valid, he supposed it would be modified by the processes by which such charters were usually modified. No other authority but Parliament could interfere. Therefore, though he had been sitting there in a position of seeming authority, he had not, nor had his friend beside him (Lord Cranbrook), any more authority or power beyond that of any member of the House of Commons or of the House of Lords. No doubt members would bear in mind what had been said. But whatever was done, he hoped that the action would not be of such a character as to put a stop to educational development and growth of this kind, and that the door would be left open for the introduction of such improvements and extensions as would bring together all the educational power and enthusiasm in this metropolis in the common search after one end.

Lord SPENCER proposed a vote of thanks to the Premier, which was accorded, and the deputation withdrew.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 25th ult. the following gentlemen received the degrees of Bachelors of Medicine and Bachelors of Surgery:—

Sydney Kent, John Dixon Stubbs, Trinity; George Armstrong Mason, St. John's; Mark Robert Phipps Dorman, Clare; William Goodenough Hawkins Bradford, Gonville and Caius; William Henry Cantrell Shaw, Jesus; Francis Gore Wallace, non-collegiate.

UNIVERSITY OF DUBLIN.—The following degrees have been recently conferred:—

Bachelor in Medicine, Surgery, and Obstetrics.—Abel Onge Eastwood. James Langton Falkner, Rudolph William Johnston, John Henry Head, Alfred H. Holmes, James Elliott Jameson, Mark Thomas Kelly, Edward Vincent Legge, Mark McDonald, Thomas Haughton Murphy, George John Peacocke, Robert Hill Shaw, Alfred Ernest Taylor, Edwin Hotham Townsend.
Bachelor in Surgery.—Abraham William Bate.
Doctor in Medicine.—Cecil Orpin, Rudolph William Johnston.

THE SANITARY INSTITUTE.—A sessional meeting of the institute will be held at the Parkes Museum on March 9th, at 8 P.M., when a paper will be read on "The Air and Water of London: are they deteriorating?" by Louis Parkes, M.D., D.P.H., medical officer of health, Chelsea. The paper will be followed by a discussion.

HOSPITAL FOR CONSUMPTION, BROMPTON.—A quarterly court of governors of this useful charity was held at the hospital on the 25th ult., Mr. T. P. Beckwith in the chair. The Committee of Management, in their report, regretted that the whole of the 321 beds in the two buildings had not been continuously occupied, the return of the influenza epidemic having rendered it necessary to reserve seven large wards, into which any patients attacked were at once transferred and isolated from the others. This for some weeks prevented many admissions, but, owing to the subsidence of the epidemic, the beds kept vacant were now being rapidly filled up. A donation of 100 guineas had been received to name a memorial bed, as also a gratuity of £545 9s. from the Hospital Saturday Fund. Dr. Kingston Fowler (senior assistant physician) had been appointed physician, in place of Dr. Fred. Roberts, whose resignation, from pressure of other engagements, had been received with sincere regret, and who in recognition of his long and valuable services was appointed consulting physician. Several bequests were announced. The number of patients admitted since Nov. 26th was 386; discharged, many greatly benefited, 316; died, 94; new out-patient cases, 3325. The report was adopted.

UNSTAMPED MEDICINES.—At West Bromwich a druggist was this week summoned by the Inland Revenue authorities for selling on five different occasions patent medicines which were unstamped. He was fined £40.

PRESENTATION.—Dr. Wm. Main of The Park, New Ferry, Birkenhead, who is about to leave the district, has been presented by his friends and the inhabitants with an illuminated address and a purse containing £180.

SWINE FEVER AT SYDENHAM. — The Board of Agriculture have had notification of a severe outbreak of swine fever in Sydenham. Out of a herd of twenty-two animals, six have been attacked and one has succumbed to the disease. The whole herd will have to be destroyed.

SMALL-POX AT DEWSBURY.—About fifty patients are reported to be suffering from small-pox in the infectious hospital at Dewsbury. The General Purposes Committee of the Dewsbury Town Council have adopted a recommendation of the Sanitary Committee that the use of part of the mansion at Crow Nest Park should be granted during the prevailing epidemic as a temporary home for convalescent patients.

NEWSVENDORS' BENEVOLENT AND PROVIDENT INSTITUTION.—At the annual general meeting, held at the Memorial Hall, E.C., Feb. 2nd, it was unanimously resolved:—"That the best thanks of this meeting are due to the proprietors, editors, and reporters of the daily and weekly press for the generous support and publicity afforded to the affairs of this society." Sir Algernon Borthwick, Bart., M.P., who was recently elected president of this institution, has consented to preside at the annual festival, to be held at the Hôtel Métropole, on Saturday, May 21st, supported by a distinguished company.

GREAT NORTHERN CENTRAL HOSPITAL. — The annual meeting of the governors was held at the hospital, Holloway-road, last week. Mr. C. T. Murdoch, M.P., presided. The report for the past year showed an increase in the number of in-patients and a very large addition to the out-patients over the previous year, the largest aggregate of patients ever treated in one year. The expenditure exceeded the year's income by £1104 12*s.* 4*d.*. There was now in hand, for the completion of the buildings, £3000, and a legacy of the same amount would be shortly paid. The estimated cost of the work was £20,000. The report was adopted.

ROYAL FREE HOSPITAL.—The work of this charity during the past year has been carried on with great success, and, with one exception, its financial position, the annual report is highly satisfactory. The in-patients numbered during the year 1886, while 12,847 out-patients and 7878 casualty cases received the benefits of the hospital. The cash statement showed an adverse balance, amounting to £3280. To meet the current expenses, a portion of the invested funds had been utilised. The appeal up to the present for £20,000, to enable the front of the hospital to be entirely rebuilt, had produced about half that sum. The reconstruction of the drainage and provision against fire were now completed. The committee are applying for a charter of incorporation, and a draft charter had been approved.

THE EAST LONDON HOSPITAL FOR CHILDREN.—The thirteenth anniversary dinner of this deserving charity was held in the Whitehall Room of the Hôtel Métropole on Feb. 24th, at 7 P.M. The Right Hon. Lord Carrington, G.C.M.G., presided, and a large number of ladies and gentlemen were present. After the usual loyal toasts had been given, the chairman proposed "Success to the Hospital," and referred in some detail to the wasting of the institution and the way in which the funds were applied. Mr. Charles Cheston, who has made a most efficient chairman of the Board of Management for more than five years, replied in an able speech. Mr. Spencer Charrington, M.P., proposed the board of management, and Mr. H. W. Trender replied. Mr. Stanley Dent read an account of the financial condition of the hospital. Mr. W. H. Battle replied on behalf of the medical staff, a toast proposed by Mr. E. S. Norris, M.P. Mr. Cowell, a consulting surgeon, proposed the Chairman. During the evening Mr. S. Whitford, the secretary, stated that £334 had been subscribed towards a convalescent home, £121 towards the building fund, and £1500 towards the maintenance fund of the hospital.

Digitized by Google

COOKERY.—The sixth exhibition of the Universal Cookery and Food Association will be held at Portman Rooms, Baker-street, from May 3rd to 7th.

THE BURTON-ON-TRENT NURSING INSTITUTION.—The report for 1891 states that it had been a year of unusual sickness. The number of cases attended was 575, and the visits numbered 15,730—an increase of 61 cases and 5320 visits. The committee had distributed £18 in bonuses among the various district nurses.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—At the next quarterly meeting of this Association, to be held in the Hall of the Faculty of Physicians and Surgeons, St. Vincent-street, Glasgow, on March 10th, at 2.30 P.M., Dr. Carswell will read a paper on "The Practical Difficulties of granting Certificates of Insanity and how they may be best overcome"; and Dr. Oswald will read a note on "Certain German Asylums."

IRISH GRADUATES' ASSOCIATION.—The annual general meeting of the Association will be held at 11, Chandos-street, Cavendish-square, W., on St. Patrick's Day, March 17th, 1892, at 5 P.M. The annual report will be presented, and the council will report its action in the matter of the Irish dispensary doctors' grievances, and the disabilities of Irish diplomates. On the same evening the Association will dine at the Holborn Restaurant at 7.30 P.M., Dr. James N. Dick, C.B., Medical Director General, in the chair.

SUSSEX COUNTY HOSPITAL.—The annual report for 1891 shows in comparison with the previous year a small increase in the number of in-patients and a large addition to the out-patients. During the year the finances had considerably improved by legacies received, which had enabled the committee to make substantial investments, and to add a sum of £2680 to the inalienable fund, whilst they had transferred £1037 to the available fund. The convalescent home continues to be a valuable auxiliary to the hospital, and the nursing institute is steadily growing in popularity and usefulness. The net profits show an increase of £142 2*s.* 4*d.* on the previous year. In the out-patients' department the refreshment bar had proved a great success.

LITERARY INTELLIGENCE.—Messrs. Churchill announce the early issue, in two vols. 8vo, of a Dictionary of Psychological Medicine, giving the definition, etymology, and synonyms of the terms used in medical psychology, with the symptoms, pathology, and treatment of the recognised forms of mental disorder, together with the law of lunacy in Great Britain and Ireland. The work will be edited by D. Hack Tuke, M.D., LL.D.—The second volume of the important work on the *Pathology of the Brain*, with clinical and anatomical studies, by Prof. Henschen, of the University of Upsala, will shortly be published by Kochler, Leipsic. The first volume appeared about two years ago, and was very well received. The workis abundantly illustrated.

MEDICAL NOTES IN PARLIAMENT.

The Commission on Tuberculosis.

IN the House of Commons, on Thursday, Feb. 25th, Mr. Chaplin informed Mr. Furness that the Royal Commission on Tuberculosis were still carrying on their investigations. Minutes of evidence had been printed for the use of the Commissioners, but had not yet been made public. He could not say when the investigations were likely to be concluded.

Pollution of the Mersey and Irwell.

This Bill, promoted by the Joint Committee of the County Councils of Lancashire and Cheshire for securing the purification of those rivers, was read a second time.

Yellow Fever at Santos.

On Tuesday, March 1st, in the House of Commons, Mr. Lawrence asked the President of the Board of Trade whether he was aware that the yellow fever at Santos had reached such a height that there was no one left to carry on business; that in consequence merchandise had accumulated to such an extent as to block the streets; that the epidemic had been aggravated by the authorities continuing to dredge the port.—Sir M. Hicks-Beach replied that the facts as stated in the question were substantially accurate. On Feb. 8th he had caused a notice to be sent to all daily papers, to the press agencies, and to Lloyd's, suggesting that, owing to the insanitary condition of Santos, no ships should be chartered for that port. He did not see that he could usefully take any further steps.

Recreation Grounds.

On the motion of Mr. Llewellyn leave was given to bring in a Bill to facilitate the provision of recreation grounds in rural parishes.

The Gresham University.

Mr. Bartley has undertaken to move that the Draft Charter of the proposed new University be not confirmed. It is understood that he will be supported by Mr. Mundella, Mr. Chamberlain, and other members of the House of Commons. In the course of the week a number of additional petitions praying Her Majesty to withold her assent from the Charter for the proposed Gresham University have been presented in the House of Commons. One petition came from Croydon, another from the Birkbeck Institution, and a third from the London Society for Extension of University Teaching.

Mines (Eight Hours) Bill.

When the second reading stage of this Bill is reached, Mr. Elliott Lees, one of the members for Oldham, will move "that this House declines to interfere with the freedom of grown-up men in regard to the disposal of their labour."

Police and Public Health (Scotland) Bill.

In the House of Commons, on Thursday, the Lord Advocate said it was the intention of the Government to introduce this Bill again. They hoped to do so in the course of a few days. The second reading must, however, depend on the condition of public business.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Dr. Percy Kidd: Examination of the Sputum for the Tubercle Bacillus.—Royal London Ophthalmic Hospital: 8 P.M., Mr. J. B. Lawford: Toxic Amblyopia.—Parkes Museum (Margaret-st., W.): 1 P.M., Dr. Louis C. Parkes: School Hygiene and Hygiene of Special Trades and Occupations.

ROYAL COLLEGE OF SURGEONS.—4 P.M. Mr. J. Hutchinson, jun.: Syphilitic Affections of the Bones, Joints, and Lymphatic System.

HUNTERIAN SOCIETY.—8.30 P.M. Pathological Evening. Mr. T. H. Openshaw: Subdural Hæmorrhage.—Dr. F. C. Turner: Malignant Stricture of Sigmoid Flexure, Secondary Growths in Colon.—Dr. Chaplin: (1) Gangrene of Lung from Pressure of Aneurysm of Aorta; (2) Enlarged Bronchial Glands producing Asphyxia.—Mr. John Poland: Epithelioma of Cicatrix from a Man aged thirty-five.

Thursday, March 10.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond-st.: 4 P.M., Dr. Arkle: Pathological Demonstration—Tuberculosis.—National Hospital for the Paralysed and Epileptic: 2 P.M., Dr. Semon: Paralytic Affections of the Larynx.—London Throat Hospital, Gt. Portland-st.: 8 P.M., Dr. Whistler: Syphilis of the Throat.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Dr. W. J. Smyly: Extirpation of the Uterus for Myoma.—Mr. Lawson Tait and Dr. C. Martin: Tubal Abortion in Ectopic Gestation.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Great Northern Central Hospital).—8.30 P.M. Dr. Patterson will show a series of Lantern Slides illustrating Surgical Diseases. Dr. O'Reilly will show a Thyroid Tumour removed by Operation, and the Patient. Dr. O'Reilly will also read a paper on an Unusual Case of Twins.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Patients and Card Specimens at 8 P.M. Dr. Rockliffe: Case of Proptosis.—Mr. Hartridge: Double Lachrymal Fistula, probably Congenital.—Mr. Work Dodd: Scleroderma of Lid and Cheek.—Mr. Hulke: Arterio-venous Aneurysm of Orbit.—Dr. Wood: (1) Disease of Retina and Choroid, with Detachment of Retina; (2) Double Coloboma in Fundus; (3) Bleaching of Eyelashes and Eyebrows in Sympathetic Irido-cyclitis.—Mr. Lawford: Reversible Spectacle Frame. Mr. Treacher Collins: On the Minute Anatomy of Pyramidal Cataract (Lantern Slide Demonstration).—Mr. Tweedy: The Physical Factor of Conical Cornea.—Mr. Kingdon: Rare Fatal Disease of Infancy, with Symmetrical Changes at Macula Lutea.

ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Victoria Embankment).—5 P.M. Dr. Francis Warner: Enquiry as to the Physical and Mental Condition of School Children. (Second Milroy Lecture.)

Friday, March 11.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

CANCER HOSPITAL (Fulham-road, S.W.).—4 P.M. Mr. F. Bowreman Jessett: Colotomy.

LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Dr. Percy Kidd: Some Forms of Myocardial Disease.—Bacteriological Laboratory, King's College: 11 A.M. to 1 P.M., Prof. Crookshank: Typhoid Fever, Diphtheria (Sections).—Charing-cross Medical School: 8 P.M., Dr. J. Watt Black: Metrorrhagia.

ROYAL COLLEGE OF SURGEONS.—4 P.M. Mr. J. Hutchinson jun.: Syphilitic Affections of the Bones, Joints, and Lymphatic System.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Damer Harrison: A case of Nerve Grafting.—Mr. Page: Peritonitis from Hæmorrhage; Abdominal Section in a case of Ruptured Spleen, and in two cases of Ruptured Liver.—Dr. Percy Kidd: A case of Mediastinal and Pulmonary Carcinoma associated with Retraction of the Chest Wall.—Mr. Arbuthnot Lane: Cases illustrating the Modes in which a Strangulated Loop of Bowel reacts to the Constricting Medium

Saturday, March 12.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

LONDON POST-GRADUATE COURSE.—Bethlem Hospital: 11 A.M., Dr. Hyslop: Legal Aspects of Insanity.

ROYAL INSTITUTION.—3 P.M., Right Hon. Lord Rayleigh: Matter, at Rest and in Motion.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE AMENITIES OF THE PROFESSION.

Perisnelt complains that, in a case of Colles' fracture which he put up temporarily till he could get a proper splint, his professional neighbour took the case out of his hands without any expression of regret or intimation. The patient was probably largely to blame, but medical men, by being neighbourly in such circumstances, can do much to teach patients to respect the profession.

Mr. Clarence Beesley.—We published in THE LANCET of Nov. 14th last a full statement by our Paris correspondent of the examinations required to be passed by foreign candidates.

Mr. J. A. Smith (Wakefield).—We confess our views are not quite in accord with those of our correspondent on the point he mentions.

DUTIES OF MEDICAL OFFICERS OF HEALTH.

To the Editors of THE LANCET.

SIRS,—I have been medical officer of health for Fulwood for about sixteen years, during which period the township has increased greatly in population and importance. It is one of the suburbs of Preston, and usually has a remarkably low death-rate, and enjoys a great immunity from contagious diseases; in fact, it may be put down as an exceedingly healthy suburban district. About a year and a half ago the County Council appointed a medical officer of health to the county of Lancaster, who immediately began to exercise a supervision over me, and requested me to furnish him with a copy of my annual report, mortality statistics, a special annual report on a form of his own, and, lastly, sent me a book of forms to fill up monthly. This happened although I never had any intimation whatever from any person in authority as to the new relationship that had to exist between me and the County Council or its medical officer of health; nor was any mention whatever made as to any increased remuneration in consequence of the evidently intended increase of work. This being so, last year I made an application for an increase of salary to the Fulwood Local Board of Health. This application was totally ignored, so when I this year sent in my usual annual report I sent therewith a letter which you will see in the copy of the *Preston Guardian* I forward to you, and which you will observe has elicited some strong comments from the chairman. My contention is:—1. I was appointed by the Fulwood Local Board of Health, subject to the approval of the Local Government Board, for three years. 2. I have received absolutely no official communication whatever indicating any new relationship between me and the County Council, or defining my duties. 3. As a matter of fact, except generally, I am not supposed to know that a County Council exists. 4. A considerable body of new work is sought to be placed on me without any indication whatever of my being remunerated for it. 5. On making application for a reasonable recompense for the extra work my application was ignored, but I was verbally (unofficially) informed that my appointment was for three years, and no application for increase of salary could be considered till the lapse of that time. 6. My appointment has never been cancelled. Under these circumstances, and as the question concerns many other medical officers besides myself, I venture to ask your advice on the above questions, and particularly on the stand I am taking in my refusal to recognise the County Council as being in any way entitled to receive any information or reports or particulars whatever from me.

Should you feel disposed to print this letter or any part of it, along with a notice of the proceedings of the Fulwood Local Board, it might elicit some expressions of opinion from other medical officers of health similarly situated as myself.—Yours truly,

JAMES A. RIGBY, M.D. Lond.,
Preston, Feb. 20th, 1892. Medical Officer of Health for Fulwood.

*** The only duty imposed upon medical officers of health, in addition to the duties which they had to perform before the passing of the Local Government Act of 1888, relates to the necessity of sending to the County Council copies of annual and certain other reports. Under Section 19 of the Act in question it is required as follows:—"Every medical officer of health for a district in any county shall send to the County Council a copy of every periodical report, of which a copy is for the time being required by the regulations of the Local Government Board to be sent to the Board; and if a medical officer fails to send such copy, the County Council may refuse to pay any contribution, which otherwise the Council would in pursuance of this Act pay, towards the salary of such medical officer." This requirement has been statutory since January, 1889, and it cannot be evaded. But it is strictly limited to copies of the actual reports in question; the County Council have no power to require any such reports to be drawn up in a special manner or according to special forms, and any compliance with such requirements as are referred to is entirely voluntary on the part of medical officers of health. Indeed, some of the suggested forms clash inconveniently with the requirements of the Local Government Board, which must be complied with.—ED. L.

Mr. J. Reiner.—(1) The second volume of the last edition of Quain and Sharpey; (2) Hartridge on the Refraction of the Eye; (3) Swanzy's Diseases of the Eye. No qualification to practise as an ophthalmic surgeon can be obtained without passing through the ordinary curriculum of medicaleducation. No one can or ought to take up a special subject of this kind without a thorough knowledge of medicine and surgery.

Mr. J. Oldfield.—The subject is doubtless of importance; but we fear its discussion in the way proposed would make too great a demand on our space.

Dr. L. G. Guthrie.—Very soon.

THE IRISH COUNTY COUNCILS BILL.

To the Editors of THE LANCET.

SIRS,—Allow me to call your attention to the retrograde provisions of the above in regard to sanitation. Fixity of tenure is not secured to the health officers. Their compulsory appointment, qualification, and remuneration are doubtful. I do not see that the Treasury is to contribute half the salaries, as is the case with the Scotch and English Acts. Free criticism on the part of the press is clearly needed.

I am, Sirs, yours faithfully,
Cashel, Feb. 26th, 1892. THOMAS LAFFAN.

"TOUTING," WITH HIGH SANCTIONS, AT CAMBRIDGE.

Cantab. complains that a handbill had been left at one of his patient's houses advertising medicine and attendance on easy terms at "The Cambridge Provident Dispensary." The list of officers is imposing, beginning with Professor Humphry as President, and including the names of Mr. Bond, chairman of the Board of Guardians, and Dr. Sidgwick, chairman of the Executive Committee of the C. O. S The names of the medical staff are given. The gentlemen mentioned above doubtless share the opinion of many that it is better that people whose wages do not exceed 25*s.* a week should have their medicine on Provident terms than on pauper or gratuitous terms. But they will agree with us that such overtures should not be made to patients of other medical men who are honourably employing them on private terms.

Dr. A. L. Griffith.—The Philosophical Transactions for 1861 published a table of weights of the human body at several ages. The table was compiled and abridged from Dr. Boyd's researches in upwards of 2000 post-mortem examinations, and was included in a communication by Dr. Sharpey to the Royal Society in the year mentioned.

Perplexed.—1. We think it does. 2. This is a question we cannot answer without seeing both agreements. Our correspondent should consult a solicitor.

DYSMENORRHŒA.

To the Editors of THE LANCET.

SIRS,—Can any of your readers suggest treatment for the following case, which has quite baffled me?

A young girl, rather anæmic, otherwise healthy, but development very backward, inclined to be hysterical at the period, has suffered for the past year at each period from agonising pain which precedes the flow, which is scanty, and lasts from four to five hours. Everything, including morphia, fails to give relief except hot fomentations, which give slight relief. The catamenia are often delayed until the fifth or sixth week. I have prescribed in turn arsenic, aloes and iron, ergotine, bromides, valerian, caulophyllin, pulsatilla, and aletris cordial, without any effect. There is considerable ovarian excitement. I am therefore persevering with bromide, but I would be glad to know of any of your readers' experience of apiol, or any hints as to treatment.

I am, Sirs, yours truly,
March, 1892. BAFFLED.

Mr. Stocker.—1. The duties of the relieving officer are numerous, and are described in Glen's Poor Law Orders.—2. The relieving officer is supposed to be at home during certain hours to give orders, but no official mention is made of his power to delegate this function to his wife or daughter, though, as a matter of fact, in the unavoidable absence of the relieving officer, orders are often signed by them.

L.R.C.P.E.—The clause is of a very extraordinary nature, and as such a clause has probably never been the subject of judicial decision, it is impossible to say what interpretation a court might put upon it; but as the assistant was presumably of full age and competent understanding, we see no legal reason why the penalty should not be enforcible.

TREATMENT OF PHOTOPHOBIA.

To the Editors of THE LANCET.

SIRS,—It might be interesting to record a novel way of treating photophobia.

A patient came to me with acute conjunctivitis, œdema of the lids, &c. He stated that having had pain in the eyes recently, he had, "to get the inflammation out," poulticed them with mustard. The inflammation has come out.

I am, Sirs, yours faithfully,
Westminster, March 2nd, 1892. FRANK HAYDON, L.R.C.P.Lond.

*** It may be necessary to remark, in reference to the above, that if a surgeon orders such an application he should give explicit directions as to how it should be used.—ED. L.

INJUSTICE UNDER THE NOTIFICATION ACT.

To the Editors of THE LANCET.

SIRS,—Referring to "B. M.'s" letter and your answer, it bears no relation to mine. Perhaps I did not make my case clear enough. I was attending a patient for cancer of the stomach, and he was attacked by erysipelas. The question was not one of diagnosis. The medical officer never saw the man, but the sanitary inspector saw him some days afterwards, and the man, who had never been informed of the nature of his recent trouble, told the inspector that he had not had it. His wife has certified by a certificate signed by her that he has had it, and that I attended him. You will see that it is no question of diagnosis, as the medical officer never saw the case. The case, I understand, is unique, and the injustice and absurdity very great.

I am, Sirs, yours faithfully,
Colchester, March 2nd, 1892. JOHN WELLER.

*** Our correspondent is clearly entitled to his notification fee, and should enforce its payment.—ED. L.

Dr. Gilbert (Baden-Baden).—It would be hardly fair to extol the merits of one preparation when there are others of the same kind in the market of equal excellence.

A CHAT ON MALT EXTRACTS,

AND

The reason why KEPLER EXTRACT is preferred by the Profession.

"MALT as a food has a great future before it." Thus, in 1885, wrote the late Dr. MILNER FOTHERGILL, and events have abundantly proved the truth of this prophecy. But although the use of Extracts of Malt has since become very general, the results of its employment have too often been disappointing. The cause of this failure may in some instances have been a faulty method of administering the article, but in the great majority of cases it is more probably to be accounted for by the use of a faulty Malt Extract. Dr. MURRELL, in THE LANCET, has written: "Extract of Malt is of such inestimable value in the treatment of all wasting diseases, both of children and adults, that any method which will help to secure the employment of good and reliable specimens must of necessity be of interest. I examined in all eleven specimens of Extract of Malt. Of the eleven, there were only two which under the conditions I have indicated would transform completely all the starch in thirty minutes, and of these one was more than three times as active as the other. Many of the specimens were of very poor quality, and possessed little or no diastasic power. Again, the late Dr. FOTHERGILL, in the MEDICAL PRESS for 1881, wrote: "Some Malt Extracts are raised to the boiling point in their preparation, and such are rendered useless as artificial digestive agents, because their diastase has been killed by so doing. In order to secure the action of vegetable diastase it is necessary to use a preparation of Malt Extract which has not been heated to more than 140° F. in its manufacture."

These facts indicate the cause of failure attending the use of many malt extracts, as they account also for the great success and deserved popularity of Kepler Malt Extract. For Kepler Malt Extract is prepared on the scientific lines above laid down, by evaporation *in vacuo* at a low temperature, and thus the activity of the diastase remains entirely unimpaired, and its utility as a digestive agent is preserved. Kepler Malt Extract is manufactured from the finest barley, and barley only, and besides being rich in active diastase, contains, in addition to a considerable proportion of the albuminates of the barley, a large amount of predigested starch (dextrine and maltose) and phosphates. Kepler Malt Extract, it will thus be seen, provides a most valuable and nutritious food and a powerful agent for the digestion of farinaceous materials.

In the case of infants, while the salivary and pancreatic glands are still undeveloped, Kepler Malt Extract, added to the food, aids the digestion and assimilation of farinaceous bodies which the child would otherwise be unable to digest. Cases of rickets and scrofula are greatly benefited by its use; while in phthisis and all other wasting diseases it cannot be too highly praised. In phthisis, Kepler Malt Extract, given with some light farinaceous food at bedtime, often gives marked relief from those troublesome complications, insomnia and night sweats.

Kepler Malt Extract is of about the same consistence as honey; it is, further, very palatable and entirely free from the sickly, nauseating flavour of ordinary Malt Extracts,—so much so that many patients take it with pleasure, while they turn from the others with feelings of repugnance. Yet another point—and a very important recommendation to persons of delicate digestion—is that the sugar contained in the Kepler Extract in the form of maltose does not readily lend itself to acetous fermentation; and on this account the weakest stomach may receive this Extract without the production of acidity and dyspepsia. Indeed, in cases of gastric ulcer NIEMEYER has employed the Extract as a food with a success which was highly gratifying.

After acute disease, the administration of Kepler Malt Extract aids digestion, promotes tissue repair, and hastens convalescence; while in chronic maladies it maintains the strength, enables the patient to better withstand the disease, and prolongs life. Used as an aid to digestion, Kepler Extract should be taken with the starchy food; or, better still, may be mixed with the farinaceous food and kept at a moderate heat for a short time before the meal is taken. Mixed with water, aërated or plain, or with milk, Kepler Extract affords a very pleasing and highly nourishing beverage.

KEPLER EXTRACT OF MALT supplied to the Medical Profession in ¾-lb. and 1½ lb. bottles at 1/8 & 3/- each.

BURROUGHS, WELLCOME, & CO., SNOW HILL BUILDINGS, LONDON, E.C.

SAVORY & MOORE'S
BEST FOOD FOR INFANTS.

The attention of the Medical Profession is especially requested to the following characteristics of this old-established **SELF-DIGESTING** *Food, which has so thoroughly maintained its reputation for superiority during an experience of 30 years:—*

Ratio of Albuminoids to carbohydrates. The ratio of the albuminoids to the carbohydrates is the same as in human milk—viz., 1 to 6·4; the ratio in cow's milk being only 1 to 3·8.

Albuminoids easy of digestion, not predigested. The albuminoids are not predigested as in pancreatised foods, but are rendered easy of digestion, leaving (as in human milk) just sufficient work to strengthen and develop the immature digestive powers, instead of weakening and abrogating them by keeping them inactive. Sir WILLIAM ROBERTS's experiments in feeding kittens show that distinct failure of nutrition occurs when the milk is predigested (peptonised), and the same thing has been observed in feeding infants, probably owing, as THE LANCET points out, to atrophy of unemployed glands.

Healthy nature of evacuations. As a consequence of the foregoing the proper peristaltic action of the bowels is maintained, and the healthy nature of the evacuations of infants fed on this food is a satisfactory feature much and favourably commented on by Mothers and Nurses.

The curdling of Cow's milk prevented. When mixed with cow's milk it prevents the troublesome curdling in the stomach which takes place when cow's milk is given alone, and assimilates its composition to that of human milk.

Complete conversion of the starch. The active Malt Diastase present provides for the rapid and complete conversion of the starch at the time of mixing into the soluble assimilable products of maltose and dextrine. The point of the gelatinisation (thickening) of the Food—viz., 140°F.—is just that at which Malt Diastase is most active, and the conversion of the starch is consequently the work of a very few minutes only.

Retention of the Phosphates and Fat. The retention of the fat and of the phosphates of the wheat and malt, which are so essential to bone formation. These exist chiefly in the outer portions of the grain, the very parts which some manufacturers pride themselves upon so successfully rejecting.

Absence of fermentable sugar. The absence of the fermentable sugar, which in the various malt extracts and milk foods so often gives rise to Diarrhœa and Flatulence.

Verdict of Jury as to inferiority of imitations. It is the *only* Infants' Malted Food which obtained a Gold Medal at the International Health Exhibition, the Jury being comprised of such authorities as Dr. ATTFIELD, F.R.S.; G. W. WIGNER, F.I.C., the then President of the Society of Public Analysts; Dr. JAMES BELL, F.R.S., the Head of the Government Laboratories; and other distinguished Medical and English and Foreign Experts. This affords significant indication of the value to be attached to the numerous imitations, which, whilst pirating the descriptive notices of the Food, utterly fail to approach its standard of excellence.

ABSTRACT OF THE

Milroy Lectures

ON AN

INQUIRY AS TO THE PHYSICAL AND MENTAL CONDITION OF SCHOOL CHILDREN.

Delivered at the Royal College of Physicians, London, on March 8th, 10th, 15th, and 17th,

By FRANCIS WARNER, M.D., F.R.C.P. Lond.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE I.

Referring to the commencement of his studies of the mental status of children, the lecturer gave his experience as to the unsatisfactory character of the signs in physiognomy, craniology, &c., when unsupported by signs of the more direct physiological action of the nerve system. As all expression of nerve states and of mental action is by movements and results of movement, it is by logical analysis of the nerve signs corresponding to such visible expression that we may hope to demonstrate the kinds of nerve action which correspond to mental states. While studying visible movement, it became obvious that certain typical postures often correspond with definite and definable physiological and pathological conditions, and might therefore be used in recording such states: this led to the enumeration of many new clinical signs. The signs of nerve action as seen in an infant were then described. In a healthy newborn infant we find movements in all its parts while it is awake—i.e., while its brain is in full functional activity. These movements may be seen in the limbs, especially in the digits, which may move separately; they are slower than most of the movements in adults, they are almost constant, and are but little under control of impressions through the senses. Such spontaneous movement Dr. Warner described under the term "microkinesis" in 1888.[1]

"When the infant is about three months old we may observe some control of its movements through the senses; the microkinesis remains as the marked character, but the combinations of nerve centres acting are to some extent coördinated by sight and sound. At the age of four or five months further evidence of control of the centres through the senses is seen; the sight of an object may temporarily inhibit the movements, and this may be followed by turning of the head, eyes, and hands towards the object seen—i.e., the coördinated movement occurs sequent to a period of inhibition of spontaneous action following stimulation. It is inferred from such observations that at birth the nerve centres act slowly and independently of one another, and the time and order of their action are not determined through the senses. At the age of five months their action may be temporarily suspended by external stimuli; and during the time when no efferent currents are passing from them to produce visible movements they undergo a change, subsequantly indicated by new and special coördinated movements. This appears to be a new and great advance in the infant's cerebral evolution. When a year old action well adapted by impressions received becomes very marked, and the child makes certain characteristic sounds on sight of certain objects, its spontaneous brain action becomes gradually more and more capable of coördination. It appears that, whereas at birth the most marked character of the nerve centres is the spontaneous action of individual loci of nerve tissue, in advancing evolution this spontaneity is not lost, but remains as the foundation of so-called voluntary and intellectual action, becoming more controllable by circumstances. Aptitude for mental action appears to depend upon the capacity of nerve cells for control through the senses, such impressions temporarily inhibiting their spontaneity, and arranging them functionally for coördinated action. The imbecile infant does not show this microkinesis in the normal degree; its nerve centres are wanting in spontaneity, and later in capacity for coördination. It may be shown that well coördinated visible movements usually accompany well-controlled mental action, while a spreading area of movement not controlled often accompanies mental confusion.

"This spontaneous movement, slightly under control, is the character of healthy brain action of children in the infant school, so that postures are less available as signs among these very young children, and spontaneous movement of their fingers is the normal. The parts of the infant are then full of spontaneous movement; an exception is in the eye movements, which are not frequent in many cases; one of the endeavours of infant training should be to encourage eye movements, then to control them. The postures or attitudes of the body imply balances, or ratios of action, in the nerve centres corresponding; the clenched fist or convulsive hand is common in fits and in tetany. These postures indicate relations in quantity of action among nerve centres. If we take the 2285 cases presenting deviations from the normal balance of the hand when held out we find that 1029 of them presented visible defects in development also—that is to say, in nearly half of these cases with unusual or defective ratios of nerve action the proportioning of parts of the body was visibly abnormal. This suggests the hypothesis that the forces or antecedent conditions which caused ill proportioning of the body may also have caused a tendency to ill balancing of nerve centres. The converse of the proposition may be true; we have not as yet sufficient evidence, but the suggestion may guide inquiry; it may be found that as overaction of the frontal muscles is very common with defects of the cranium, and overaction of the frontals is largely the outcome of want of mental stimuli, further culture of the mental faculties will improve the average cranial development and lessen overaction of the frontals at the same time.

"If we take the 5487 cases with abnormal nerve signs, we find among these 3071, or 55 per cent., who also present defects in development; conversely among the 5851 cases of defects in development, we find 3071 cases with abnormal nerve signs—i.e., 52·4 per cent. If we take cases with two defects in development, such as are given in Lecture IV., we see that they are correlated with nerve signs in percentage varying from 44·5 up to 71·8. The general statement that mal-proportioning in visible parts of the body and abnormal nerve signs are often coincident may be further illustrated, and such inquiry may lend some support to the hypothesis that both kinds of defects may be due to the action of physical forces controlling quantities or ratios of vital action. In rickets there is a marked tendency to mal-proportioning in the skeleton; this is seen in epiphysial overgrowth, in unequal bilateral growth of the shafts of bones producing curvatures, and in the skull producing bosses and deformities. This tendency to mal-development may affect the features and soft parts. Among 196 rachitic children fifteen were small in growth, and forty presented defects of ear, epicanthus, features, palpebral fissures, mouth, &c. This also is a condition that falls much more commonly upon the boy than the girl. About one-third of these mal-proportioned rachitic children presented abnormal nerve signs and mental dulness.

"In observing conditions of development and physiognomy as indications of probable conditions of mental status—as in older physiognomical studies,—the assumption is made that visible conditions of defect in form more or less necessarily coincide with defective brains. Such correspondence does doubtless often occur, but the generalisation is too empirical to be applied with safety to the individual child. Here the observation of a number of abnormal nerve signs helps to supply the missing link, and observations quoted show that among children with defects in development and abnormal nerve signs one-third are reported by the teachers as dull at school lessons. In the report prepared on 50,000 children and in quotations from it, the term "defect in development" is frequently used; this signifies deviation from the average or normal. It is not intended to assert that these signs are degenerations—the evidence derived from antique works of art shows that many are of ancient date,—it appears that in some classes they may be irregularities which further evolution, if wisely guided, may remove with their attendant evils. Among the 2961 Jew children, an ancient race, uniformity of development was

[1] Proceedings of the Royal Society, vol. xliv. Journal of Mental Science, April, 1888.

Digitized by Google

very marked with 7·5 per cent. of deviations from the normal, and all points in nutrition, nerve action, and mental status appeared more regular among them than with our English children. When it is pointed out that of English children 10·8 per cent., and of the Jew children 7·5 per cent. present deviations from the average development, it is obvious the proposition may be put thus: the English children to a percentage of 89·2 and the Jew children to a percentage of 92·5 have evolved an average type.

"It is very usual to see disordered conditions of the nerve system in children with defective construction of body; this was the case in 3071 children. We may also see these nerve disturbances in children of normal construction of body. This was noted in the report in 2416 children; here such signs would appear to result from the disorder produced by special circumstances rather than from defects in original construction. In illustration, children fatigued and in the condition of chorea may be described. Among the signs of fatigue are the slight amount of force expended in movement often with asymmetry of balance in the body; the fatigued centres may be unequally exhausted, spontaneous finger twitches like those of younger children may be seen, and slight movements may be excited by noises. The head is often held on one side; the arms when extended are not held horizontal; usually the left is lower; the hand balances in the weak type of posture often again more markedly on the left side. Facial expression is lessened, and the orbicular muscles of the eyelids are relaxed, leading to fulness under the eyes, while the eyes themselves fix badly.

"'Nutrition' is a somewhat vague word; as applied to children in this inquiry 'low nutrition' implies that the child as seen was thin, pale, or delicate-looking. It is not sufficient evidence as to good nutrition to look at the face only; this part may be well nourished, and yet the limbs may be thin. I usually felt the child's arms or legs. The most important fact noted with regard to these cases, which amounted to 2003, is that 1459, or 73 per cent., were cases presenting visible signs of deviations from the normal in development of the head, the features, and other parts.

"It seems, then, that there is a large group of children, amounting to nearly 3 per cent. of the children seen, who are so far defective in make as to be usually of low nutrition when seen in school. This fact is more marked in the 36,000 children in day schools; among them 23 per cent. of the boys and 38 per cent. of the girls who presented defects in development were noted as of low nutrition. It appears that these children are of lower general constitutional power, and tend to an ill-nourished condition under the stress of life and the many causes of mental excitement, which, while they render them sharper mentally, militate against nutrition of the body and its tissues. That the amount of mental stimulus received by children does lower their general nutrition seems to be further indicated as follows. If we divide the 36,000 day scholars into two groups, of 10,200 seen in day schools of the upper social class, presumably well-fed children, we find 5·2 per cent. of low nutrition, and among the 25,800 children in poorer day schools 3·9 per cent. The only explanation to be offered is that the upper-class children have more stress upon them than those of poorer social position. This subject will be pursued later on.

"*Methods of observation and research.*—The methods of examining the physical condition of children seen in schools must necessarily be more limited than those used in the consulting room. Arrangements already exist in the reports of Her Majesty's inspectors for determining the intellectual acquirements of school children; their family history and evidence as to their home life could not be obtained, and school managers naturally object to questions being asked of the children concerning their health, which, if put, would not be likely to elicit any trustworthy information; it is also impracticable to handle the children for the purposes of physical examination. The observer must then depend mainly upon inspection, and having determined beforehand what points to look for, he must record accurately what he sees. The importance of deciding on a number of physical signs for observation and record was appreciated before the work was commenced on a large scale. For the purpose of observing those finer balances and reactions of the nerve system which indicate neuro-mental potentialities, it is better to deal with the children in a uniform manner and not to handle them. The terms used in giving descriptions of children should each connote a fact seen and capable of verification and comparison, the essence of scientific description.'

A Clinical Lecture
ON
A SUCCESSFUL CASE OF CHOLECYSTOCOLOTOMY.

Delivered at the General Hospital, Birmingham,

BY THOMAS F. CHAVASSE,
SURGEON TO, AND LECTURER ON CLINICAL SURGERY AT, THE HOSPITAL.

GENTLEMEN,—This patient, a painter by trade, aged forty-seven, was first brought under your notice on Oct. 23rd, 1891. The clinical history then detailed to you showed that in May last he was transferred to the surgical wards by my colleague, Dr. Simon, in order to undergo the operation of cholecystotomy, as his symptoms and intense jaundice were attributed to gall-bladder concretions. On May 25th, 1891, the abdomen was opened, and the gall-bladder was found to be deeply situated under an enlarged right lobe of the liver. On incision, eighty gall-stones of various sizes, weighing, when dried, ninety grains, were removed. One of these, the largest, was very firmly impacted low down in the common bile-duct, and was only with difficulty removed after chipping off small portions at its edges. The wound healed well, leaving a small sinus at the lower extremity of the incision, and the patient left the hospital on June 28th. From time to time he was seen in the out-patient department, but as the small fistula remained patent, several pints of bile were daily discharged through it, causing an eczematous condition of the surrounding skin, great physical discomfort, and inability to earn a livelihood. By his own request he again entered the hospital, in order to undergo further operative treatment. When exhibited he told you that so long as the fistula was open and the escape of bile was free he experienced no pain, but when the external opening scabbed over he had violent pain, high fever, and on several occasions rapidly supervening jaundice, only relieved by measures that re-established the external biliary flow; that his stools were regular, but always clay-coloured, unformed, and offensive; and that the average quantity of urine passed in twenty-four hours was under thirty ounces. Your attention was also directed to the fact that, although the bile had been escaping externally for several months, the patient was apparently in good health, well nourished, not to say stout, and had an excellent appetite, which he satisfied in a manner most agreeable to himself, without any serious consequences, provided the escape of bile externally was encouraged. On inspection, at the termination of the lower end of the cicatrix of the former incision, a fistula was found, its very minute orifice admitting with pressure the smallest sized Bowman's probe. From this small opening bile was constantly oozing; the exact quantity it was difficult to estimate; but an absorbent dressing, consisting of cotton and wood-wool pads, which, on being first applied in the morning, weighed 11 oz., in the course of twenty-four hours increased to 35 oz.

On Oct. 24th an effort was made to close the fistula by means of the following operation:—The cicatrix in the abdominal wall was cut through, the incision being prolonged downwards one inch below the orifice of the fistula, into which a fine probe had been inserted. The gall-bladder was separated as freely as possible from its adhesions, a step which caused free oozing of blood. The anterior wall of the organ, presenting the appearance of fibrous tissue, was opened up from the fistula, so as to admit the points of two fingers. A very small gall-stone, the size of a split pea, black and friable, was found at the internal opening of the sinus, and removed. The inside of the viscus presented no remains of anything that could be called a mucous coat. The common bile duct could be felt like a thickened cord, but no stone could be detected as far as the finger could be passed along its under surface, and a probe introduced from the external wound could not be made to travel as far as the finger could reach, and it was not deemed desirable, for obvious reasons, to exercise force. The ascending colon was therefore sought for and readily exposed. Trusting merely to the sponge packing of the abdominal cavity, no clamps of any description being used, the anterior wall of the bowel was incised near its flexure at a point where it could be most readily approximated to the under surface of

Digitized by Google

the gall-bladder. A Senn's bone-plate was then inserted into the bowel, and an incision made into the under surface of the gall-bladder. Another of Senn's plates, pared down to suit the capacity of the viscus, was then introduced into the gall-bladder through the opening in the anterior wall, and the mucous coat of the colon was stitched, with two interrupted catgut sutures, to the edges of the incision on the under surface of the gall-bladder. The two bone-plates were then approximated in the usual manner and a pair of dressing forceps inserted into the colon from the gall-bladder, in order to prove that a free communication had been established between the viscera. The edges of the old fistula were then refreshed and the anterior wall of the gall-bladder sewn up by a continuous catgut suture and two interrupted ones of the same material. A large glass drainage-tube was introduced into the right kidney pouch at the lower extremity of the external wound and the peritoneal and abdominal wounds closed in the ordinary way, a dressing of cyanide gauze and corrosive sublimate wool being applied.

After the operation the patient was restless, and in the first seven hours three ounces of fluid, almost pure blood, were drawn off from the drainage-tube. A drachm of hot water was administered by the mouth every hour, and there was no vomiting. For the next two days the patient is reported as being comfortable, the wound sweet and healing, and two ounces of blood-stained fluid drawn off through the drainage-tube every twenty-four hours. On Oct. 27th the note is as follows: "Wound looks healthy, but there is a slight fæcal odour about it; stitches removed from upper portion and strapping applied; from the tube an ounce of fluid escaped, of a yellowish-green colour and faint fæcal odour." The following day there was a distinct fæcal smell about the wound, and also in the fluid withdrawn from the tube. The temperature taken every four hours never rose to 100°F. On Oct. 30th, at 8 P.M., the dressings were found soaked with bile, the nurse's attention being drawn to the same by the patient telling her that he had just felt something give way and a rush of fluid take place externally, as before the operation. On removing the dressings bile was seen issuing from a small orifice just above the drainage-tube, together with a small quantity of clay-coloured fæcal matter. A simple enema resulted in a copious dirty-brown-coloured stool, not offensive. From this date till Nov. 2nd, on which day the drainage-tube was withdrawn, the discharge was profuse, and owing to the dressings being soaked they had to be changed three times in twenty-four hours. On the evening of Nov. 5th an aloes pill (five grains) was given by the mouth, and on the following morning the bowels were twice freely moved through the fistulous opening in the abdominal wall without any pain, nothing passing per rectum. After this a simple enema was given daily, the lower portion of the wound slowly granulated, the bile and fæcal matter passed by the fistula gradually lessening in quantity, and ceasing entirely on Nov. 20th. By the 29th the wound had healed, and the patient was allowed to get up. His fæces now are of a soft brownish colour, but not offensive, and are evacuated daily without artificial aid. Since Nov. 18th the average quantity of urine passed in twenty-four hours has been fifty-eight ounces; the appetite, digestion, and sleeping powers are all that could be desired.

From the persistence of the fistula it was evident that the lumen of the common bile duct was practically obliterated, the result, probably, of inflammatory changes, as a thorough exploration at the second operation failed to detect any impacted gall-stones. That this duct may be so strictured is proved by a case operated on by Dr. H. C. Dalton of St. Louis,[1] for empyema of the gall-bladder, in which the post-mortem examination revealed a circular cartilaginous ring one inch and a half distant from the duodenum, which completely closed the tube. This condition was attributed to an ascending enteritis. In the case just recorded the irritation caused by the existence of impacted gall-stones, and the manipulation necessary for their removal, are, I think, quite sufficient to account for the obliteration of the lumen of the canal.

Given the presence of this stricture, the following methods of treatment are suggested:—

Dilatation, as recommended by the late Professor Parkes,[2] by forcing a steel sound through the stricture, a finger in the peritoneal cavity guiding the point of the instrument. This is an unsatisfactory proceeding, for, even if successful, it is probable, as in the strictures of other mucous canals, that it would need repetition to preserve patency, and this could not readily be undertaken. Another objection is that the duct itself might be perforated by the force required, and then some other proceeding to divert the bile would have to be undertaken. It is better, therefore, to proceed at once to establish an artificial channel between some portion of the bowel and the gall-bladder, and the choice lies between the small and large intestine. By the method described the operation was carried out in its entirety at one sitting, but in the earlier cases some of the operators have deemed it advisable to subdivide it into two or three steps, not establishing the communication between the gall-bladder and the bowel until adhesion had taken place, and then resorting to a plastic operation to close the external wound in the abdominal wall. In 1880 Professor v. Winiwarter[3] had under his care a workman, thirty-four years old, in whom he brought up and secured the ascending colon to the gall-bladder, and four days later established a fistula between the two by means of a trocar. But the external wound not closing later on, in November of the same year he reopened the abdomen, and fixed a coil of the small intestine to the gall-bladder and established a second fistula. Both fistulæ remained patent and bile and fæces were discharged on to the abdominal wall. A year later (Nov. 1881) an effort was made to close externally both fistulæ by means of a plastic operation. This was successful as regards the small intestine, but that connected with the colon only granulated slowly after many cauterisations. But in a year and a half the patient was quite sound.

In 1887 Kappeler[4] had a male patient aged fifty-five in whom the common bile-duct was closed by the pressure of a tumour connected with the pancreas. The operation of cholecystotomy was performed and 350 grammes of bile evacuated. An effort was made to reach the duodenum; but, owing to the enlargement of the liver and the depth at which this portion of the gut was found to be situated, it was deemed prudent not to attempt to connect it with the gall-bladder, but a presenting coil of jejunum was readily drawn up, incised, and its serous and mucous coats stitched to corresponding surfaces of the gall-bladder. The wound healed in a month. Professor Socin has similarly operated upon a woman aged fifty-one with complete obliteration of the common bile-duct and dilatation of the gall-bladder. Professors Tillaux and Terrier have also had successful cases. In this country, Mr. Mayo Robson[5] has published a case in which he successfully closed a biliary fistula that had existed for fifteen months in a woman aged forty-three, upon whom it was necessary to perform cholecystotomy for empyema. In this case the hepatic flexure of the colon was emptied of its contents, and clamped between two elastic ligatures, to prevent extravasation during the necessary manipulations. The gut and gall-bladder were then opened, and their mucous and serous coats separately secured. As in my case, bile and fæces subsequently escaped externally, but in two months the wound had quite healed. Mr. Alfred Willett,[6] in some remarks upon a case of his in which a biliary fistula remained after the gall-bladder had been incised for empyema, thinks it would be advisable to make use of the colon rather than the small intestine, as it is nearer the gall-bladder, easier to reach, and gives more space for the necessary manipulations. He likewise points out that a fistula established in connexion with the duodenum might result in the regurgitation of bile into the stomach. The practical experience of a single case leads me to believe that a coil of the jejunum or the hepatic flexure of the colon are the two most accessible for utilisation. Physiologically, the former should be preferred. But as my patient had passed some months of his life without any bile entering his small intestine, had eaten and drunk whatever he pleased, and in spite of the annoyance of an active biliary fistula had maintained his general health, I resolved to open whatever portion of the intestine should appear most advantageous at the time of the operation. On examination the ascending colon was found almost touching the gall-bladder, immediately beneath it, and although the jejunum could have been drawn up to the viscus a loop would have been formed, somewhat stretched and out of position, lying over the great

Digitized by Google

gut, possibly of no consequence, but perhaps liable to pressure if the colon became much distended. This decided me to open the large intestine. No elastic ligatures were used, as in Mr. Robson's case, as it was thought that a thorough sponge packing of the abdomen would prove effectual in keeping the peritoneum from being soiled, and also that the insertion of a Senn's plate directly the gut was incised would offer a firm point for sponge pressure whilst the gall-bladder was being prepared. This expectation was fully realised, and the ultimate result proved satisfactory to both patient and surgeon.[7] These biliary fistulæ are rare; for, as a rule, after the operation of cholecystotomy, unconnected with malignant disease, the wound heals quickly and well provided that the common bile-duct is patent. For this reason I would impress upon you the desirability of counselling patients, when sufficient evidence has accumulated to make the diagnosis of retained gall-stones possible, to submit to the operation for their removal. For, as in other chronic diseases of the internal organs in which time, rest, and climate fail to relieve, surgery must be resorted to for palliation or cure. The irritation caused by the retention of one or more gall-stones may possibly be a factor inducing malignant disease of the liver, and a calculus firmly impacted in the common bile-duct, in its efforts to reach the duodenum, is a serious complication in cholecystotomy necessitating crushing, as advocated by Mr. Tait, or incision and suturing of the duct as successfully carried out by Mr. Knowsley Thornton, or a series of manipulations, such as boring or chipping off pieces of the stone to permit of its extraction, all of which may directly and indirectly result in a stenosed condition of the duct, and subsequently rendering such an operation as we have been considering imperative. To describe the method here carried out I have used the term "cholecystocolotomy" in preference to that of cholecystenterostomy, employed by other writers, as pointing out definitely that the fistula was established in connexion with the colon.

In conclusion I have to express to my house surgeon, Mr. James Lea, B.A., M.B. Cantab., the indebtedness of the patient and myself for the time, the skill, and unremitting attention he so willingly devoted to the case.

[7] The total loss of weight from May to the end of December was just under two stones.

ON AMPUTATION AT THE HIP-JOINT; WITH RECORD OF TEN CASES.

By RICHARD DAVY, F.R.C.S. Eng., F.R.S.E.,
SURGEON TO THE WESTMINSTER HOSPITAL.

FOR fifteen years I have been most interested clinically in cases of hip-joint disease that demand surgical severity. I trust that a summary of my experience may have a practical value, and may render somewhat less the anxiety and responsibility of surgeons undertaking this the gravest amputation of all—viz., amputation at the hip-joint. The gravity of such procedure ought to forcibly impel surgeons to take measures to prevent its necessity. Early diagnosis of ilio-femoral disease, intelligent treatment, and perseverance with general and local measures should be written in bold type on the title-page of its history. Yet, in spite of warning, care, and weariness of well-doing, cases eventuate whose only solution rests in ablation of the joint or of the limb. Traumatism plays an important initial part; insanitation and poverty supplement it; an amputation at the hip-joint amongst the well-to-do classes is almost unknown, bearing out the accepted dogma, that "circumstances alter cases." Let us take an instance where continued and exhaustive suppuration, hectic, hill and dale on the temperature chart, emaciation or commencing lardaceous disease of the viscera compel interference; then as a rule it is better to excise the joint in view of giving a patient the chance of improving, and as a preliminary step in any future operation. Yet personally I do not view excision of the hip-joint very favourably in any but young subjects; children up to and below ten do admirably after excision of the hip; over that age the dangers are greater, and the ultimate usefulness of the limb not so good.

The record of my own personal experience shows that I have operated on ten patients in fourteen years, all except one have been markedly inveterate cases of morbus coxæ; four of them had suffered excision prior to amputation at the hip-joint, profuse suppuration and resultant enfeeblement have been the immediate conditions necessitating amputation; all these doubly operated upon patients have recovered, one good argument in favour of subdividing an amputation at the hip-joint into two stages, as advocated by Keetley; the mortality is 20 per cent; both were men, aged twenty-nine and forty-three respectively. Two of the patients have subsequently died, one eleven, the other eight years after operation. The first of these (Case 2 on the table) was supposed to have had lardaceous disease of his viscera, at any rate he had copious albuminuria and epithelial casts in his urine in 1878. In speaking of this boy in 1880 it was remarked: "This boy had lardaceous disease of his viscera, with distressing ascites. The rectal lever was used. It would have been impossible to compress his aorta or common iliac artery through the abdominal wall, by reason of the distension. This boy's recovery is pleasing, and the albumen in his urine is daily diminishing." On April 7th, 1890, he was readmitted into Westminster Hospital from Dr. Barnardo's Home, the subject of urgent and uncontrollable sickness, with a puffy and discharging right stump of thigh, and an œdematous foot (left). His urine was albuminous, alkaline; sp. gr. 1016. The patient passed about 11 oz. of urine in twenty-four hours, and there was persistent diarrhœa. On May 1st a piece of bone was removed from the stump and sinuses were laid open. He got weaker, duller, and more helpless, dying on May 23rd, 1890. Appended are Dr. Hebb's notes of the necropsy. "These I need not state fully, but will give an excerpt. The kidneys weighed 9½ oz. and 9¼ oz.

† Ambulanced to Harlington. Death in the Royal Free Hospital from pelvic necrosis on Feb 6th, 1890

Digitized by Google

right and left respectively. They are typical examples of large white kidney. None of the viscera present any of the characteristics of lardaceous disease, nor do they give any amyloid reaction with iodine." We see therefore how difficult it is to diagnose lardaceous disease in these exhausted surgical cases. Case 5 died on Feb. 6th, 1890, eight years after operation, in the Royal Free Hospital, of pelvic necrosis. I positively declined to see the complete post-mortem examination on this boy's body because the post-mortem room was filled with women. In my opinion women are quite out of place in the deadhouse of any general hospital. So, as they would not leave, I did.

Method of operating.—In 1880 (Surgical Lectures) I stated: "With reference to the method of operating I shall only advise you to exercise common sense, and apply it to each individual case; keeping the skin intact where the scrotum rubs the thigh, saving as much soft tissue as you possibly can, and having your front flap covering the wound epaulette fashion, for the production of a dependent drainage, and the utmost simplicity of future dressing." Furneaux Jordan, in recapitulating the essentials of his operation, says, "I conclude by again repeating the principle of the operation—enucleate the bone where it is most thinly covered; cut across the soft parts where they are smallest; do not touch the bulky soft parts at the inner and upper parts of the thigh."

Professor Ollier of Lyons did this operation in 1859, but the credit of bringing the method prominently before surgeons is, in my opinion, greatly due to Furneaux Jordan. The lever or elastic tourniquet having been applied, a circular incision is made at about the upper third of the thigh, through all the soft structures down to the femur; the lower section is drawn down forcibly towards the knee, to give space for the ligation or torsion of vessels. The bone is not divided, but kept intact for future leverage in disarticulating at the hip-joint (a most valuable act of conservatism). After all vessels are carefully secured an external wound is made right down to the shaft of the femur; the muscles around the trochanter major and the shaft of the bone are freed from their attachments; utilising the under surface of the rectus femoris as a guide, divide the psoas and iliacus on the capsule of the joint, as well as the capsule itself, by a long anterior slit and two short crucial nicks. The assistant then rotates the limb outwards, and forcibly adducts the knee towards the opposite armpit to dislocate the femur from the pelvis. By the yet further availableness of the limb and femur as a lever the member is removed by a few well-directed touches of the knife, any vessels which may have been injured are promptly secured, the acetabulum is scraped, if necessary, the wound is thoroughly syringed with hot water and corrosive sublimate solution, stitches are put in, and the patient is at once conveyed to a warm bed. Use all proper speed in operating short of hurry. "Festina lentè" is a good motto for convenient haste. Only one word about the lever. Nine out of these ten cases have submitted to its employment. The elastic bandage in the hands of a competent assistant is quite sufficient to control any hæmorrhage, and especially so in those cases where excision of the joint has preceded amputation. The elastic cord must be applied obliquely, spica fashion, and be manipulated so as not to interfere with abdominal respiration. The use of the elastic cord is absolutely free from danger; that of the lever is not.

Let me correct an error that has frequently been expressed, that an amputation at the hip-joint involves a loss of nearly one-fourth of the human frame. I have already contradicted this, and can adduce chapter and verse on this point. On Jan. 20th, 1891, I amputated at the hip-joint of a boy aged fourteen. The weight of the parts removed was 41b. On Feb. 19th, 1891, I weighed the boy—as soon as I felt it safe—and his body weighed 501b. Admitting that he might have gained 21b. in weight since the operation, we have the proportion of tissue removed to tissue saved as 4 to 48. This reduces the mutilation to one-thirteenth of the boy's body—a great difference from one-fourth. The point of selection (upper third of thigh) as now practised necessarily makes the comparison favourable; for in olden days the catlin entered at the anterior superior spine of the ilium, and emerged near the tuber ischii, slap-dashing off the limb by two flaps.

On Oct. 17th, 1881, the late Mr. Shuter amputated a boy's left thigh at the hip-joint[1] by a subperiosteal method. In 1882 the boy had a strong movable stump, and it had the appearance of an amputation in the middle third of the thigh. An artificial limb was made for the boy by Mr. Gray. This was worn for five months, and it had to be discontinued by reason of a painful sinus, which opened opposite the acetabulum. The case was exhibited on Feb. 9th, 1883. The committee appointed to report on the condition of the boy's stump state that by "the preservation of the muscles of such a length, and with their attachments becoming so firmly united around a strong central cord, the result obtained approaches that of an ordinary amputation at the upper third of the thigh, in respect both to the facility of adapting an artificial limb and the power with which the patient can move this appliance when walking."

My patients are all walking with the aid of crutches, except one, who has an artificial limb. For working folk crutches are such a support, such a warning to outsiders, so easily discarded or resumed, and so comparatively cheap, that practically they are preferred in cases of this nature.

The explanation of the reduced mortality from 60 to 20 per cent. appears to be a general one.

1. The use of anæsthetics. We are too apt to forget the benefits handed down to us by previous workers better than ourselves, and to pocket their results as if they were our own. The patient being free from pain, permits a more careful and studious dexterity on the part of the surgeon, and lessens the shock on the part of himself. 2. The more rigorous application of measures calculated to prevent the loss of blood; such as the lever, elastic bandage, torsion, and the composed conduct of dressers. 3. The diminished shock, by adopting the method of operating at the juncture of the upper and middle third of the thigh instead of the old high transfixion plan; the less risk of hæmorrhage (primary and secondary); and the uninjured condition of parts at the inner side of the thigh, situated in the confines of Scarpa's triangle. 4. Improved sanitation, nursing, and hygienic surroundings; more skilful dressings; marked cleanliness and the use of the syringe. 5. The greater quiet of isolation, the careful selection of cases for operation, and the better sustained discipline preparatory to and after the operation.

Let me again advocate every possible trial on the part of the surgeon to prevent the necessity of recourse to amputation at the hip-joint. Should such necessity occur as a last resource for saving life, let the operation be done on somewhat similar lines to what has been narrated in this paper; let it be completed with resolution and composure. Then, after the daily and nightly care of surgeon and nurse, for may be weeks or months, the patient will be able to walk on crutches or with the aid of an artificial limb, and enjoy a further lease of life.

IODODERMA, OR DERMATITIS TUBEROSA, DUE TO THE INGESTION OF IODIDE OF POTASSIUM.

BY NORMAN WALKER, M.D., M.R.C.P. EDIN.

THE following case, which occurred in Dr. Unna's clinic last summer, and which Dr. Unna kindly handed over to me for investigation, is one of considerable interest, for although several cases have been clinically described, the pathological histology of the new growth has, with a very few exceptions, remained uninvestigated.

J. E——, male, aged forty-one, married, was admitted on July 21st on account of a rapidly growing tumour situated on the lower part of the nose. He has always enjoyed good health. He has had gonorrhœa at least twice, and seven months ago he acquired a sore on the penis, which, he says, healed up under the application of cupric sulphate, and gave him no more trouble. His glands are everywhere hard, but not much enlarged. He never had any cutaneous eruption or loss of hair. His urine contained no albumen. The history of the present affection is as follows:—On July 8th, on account of a feeling of dryness and discomfort in his throat, he consulted a laryngologist, who prescribed for him a mixture containing iodide of potassium, of which he was to take doses amounting altogether to seventy-five grains a day. The throat affection improved, but on July 13th a small nodule appeared on the bridge of the

Digitized by Google

nose. It was red and inflamed looking. On the 14th it had grown larger, and he squeezed from it what he describes as matter and blood. Later in the day a ring of vesicles appeared round the original nodule, and, as next day the growth still increased, he revisited his doctor, who ordered him to apply to it Hebra's Diachylon ointment. On the 16th, as it was still larger, a dressing of lint was applied and the doses of iodide increased, so as to amount to 100 grains a day; but the tumour continued to increase in size up to the time of his entering the clinic.

The tumour was situated on and occupied the lower half of the nose. It was of a dark-yellowish or orange-red mahogany tinge, with here and there lighter yellowish spots. It was in appearance granular, and here and there

FIGS. 1 & 2.

Full face and profile views before operation.

were what looked like the openings of sebaceous glands. It was elevated about a third of an inch above the normal level of the part, and looked just as if a piece of coloured and varnished putty had been stuck on the end of his nose. It caused him no pain. Its appearance at once suggested that of an epithelioma. On touching it, however, this impression was dispelled, as the tumour was of an extraordinarily soft and sponge-like consistence. Manipulation was also painless. The diagnosis, excluding epithelioma, was thus limited to three possibilities: mycosis fungoides, syphilis, and a dermatitis due to medication. Against the first two were the rapid growth and the unity of the tumour, with the addition, in the case of mycosis fungoides, of the fact that there had been no preceding skin affection, and the production of the prescription for the medicine, which had been taken so freely for almost a fortnight, put the diagnosis, which had been already made by Dr. Unna, beyond doubt. The medicine was at once stopped, and for a few days the tumour was left to itself. With the exception that it became somewhat darker, things remained very much *in statu quo*, and consequently on July 25th the patient was put under chloroform, and the natural shape of the nose restored by removing the superfluous growth with a razor. The cut

FIG. 3.

Condition fourteen days after operation. The white appearance in the engraving taken from the photograph is due to the staining by pyoktanin.

surface bled very freely, to which a Paquelin's cautery was applied, after which it was painted over with an alcoholic solution of pyoktanin. The wounded surface healed very rapidly, and on Aug. 2nd, with the exception of a small area in the centre, the skin looked as healthy as that of the rest of the nose. This central area had a warty nodular appearance, as if there still remained in it some excessive epithelial activity. Resorcin plaster was applied to shell off the outer layer of the epidermis; but as this central part remained somewhat obstinate, it was destroyed by the application of pure carbolic acid. On Aug. 9th the patient returned home with his nose practically as well as it had been before the appearance of the tumour.

In considering this case in relation to its commencement, its history, and especially to its after-progress, one can have little doubt that a correct diagnosis had been arrived at in the first instance. The microscopic examination, interesting as it is, gives little help in establishing the diagnosis, as the removal of a portion of the new growth for histological purposes seems hardly to have occurred to the majority of those who have clinically described this condition. Mr. Jonathan Hutchinson[1] says, in reference to the fatal case which he publishes in his Archives, that "the microscope was carefully used, but revealed nothing of importance."

Brocq[2] enumerates nine varieties of skin eruption which may be caused by the administration of iodine:—1. Diffuse erythematous. 2. Papular urticarial. 3. Vesicular and eczematous. 4. Pemphigoid. 5. Papulo-pustular. 6. Anthracoid. 7. Petechial. 8. Nodular or tubercular. 9. Polymorphous form. The form of eruption which is popularly, and probably most frequently, associated with the administration of iodine is the vesicular and bullous form, while the condy-

Digitized by Google

lomatous, tubercular, or anthracoid form, though it has been not infrequently remarked by acute observers, has apparently attracted so little general attention that more than one of the most recent text-books of dermatology leave it absolutely unnoticed; although its resemblance to syphilitic processes, and the fact that iodine is usually exhibited in its larger doses on account of that disease, make its importance difficult to over-estimate.

The first reference, though not a very direct one, to this (tubercular) form which I can discover is an allusion by Ricord[3] as far back as 1842, who notes that a papular or nodular erythema may be caused by the administration of iodine. Fischer[4] describes a nodular among other forms of iodine eruption. He described it as consisting of papules slightly raised, regularly rounded, and of an intensely red hue. He considered it to be a sort of telangiectatic condition such as is seen in congenital nævus, and in a more marked degree in frambœsia. The attention of the profession was recalled to this condition by Tilbury Fox,[5] who described it as consisting of a pultaceous fungating mass which he characterised as "odd." He says: "The bullous form breaking down can produce mushroom-like masses varying in size from a pea to a shilling."[6] Colcott Fox[7] applied to the eruption the term "condylomatous." M. Hardy[8] briefly alludes to an erythematous form of eruption which may possibly have been an early stage of this form. McCall Anderson[9] gives a note of a fatal case of purpura, and an interesting allusion from Voisin, who, in six out of ninety-six epileptics treated with bromide, observed: "An eruption in the form of oblong or roundish swellings on the lower limbs, of a rose or cherry colour, which became yellow, and then developed little points like acne pustules." This eruption differed from most described cases caused by iodine in that the bases were very hard and painful.

One of the best clinical descriptions of the eruption is that by Nevins Hyde[10] of Chicago, who at different times has described three cases:—Case 1: An infant where there were isolated whitish and reddish-yellow nodules varying in size from a split pea to half a marble, and resembling molluscum tumours. On the left cheek was a patch as large as the section of a turkey's egg, surrounded by a narrow areolar blush, and raised about 6 mm. above the surface.—Case 2: Child, aged two years, with face and hands thickly studded with firm reddish-yellow, slightly umbilicated semi-solid lesion, varying in size from a small marble to a pigeon's egg.—Case 3: A most interesting case, where the diagnosis of leprosy had been previously made. For more than a month the patient, a girl aged seventeen, who had not yet menstruated, was dosed with iodide of potassium. The eruption appeared on the third day of the administration of the drug in the form of a number of semi-solid papules on the forehead. These rapidly increased in size and in number, and when Dr. Hyde saw her, the patient's scalp was covered with tubercles as large as pigeon's eggs, pressing on each other, and covered with a sticky puriform mucus. The head, chest, neck, and back were covered with superficial small egg-sized, semi-solid discrete or confluent oval or irregular tubercles, raised several millimetres above the surface. Many closely resembled condylomata. A few had the appearance as though they contained boiled sago grains. Incision gave exit to blood, grumous pus, and tissue débris. The lesions could in no sense be said to be chambered. He remarks, "They were evidently masses of softish vascular epithelium." He concludes that the iodine eruption may be manifested in three forms—(1) bullous, (2) polymorphous, and (3) occurring only in infants and young persons neither cachectic, syphilitic, or moribund, but often otherwise healthy—semi-solid, slightly umbilicated lesions resembling condylomata and molluscum.

Hallopeau's[11] case differed very markedly in many points from Hyde's. The patient was an elderly man markedly syphilitic, who had on that account had large and prolonged dosing with iodide. The eruption consisted of two elements, cicatrices and vegetations. The vegetations which are the elements with which we are concerned were very variable in size up to several millimetres in diameter. Some were small and pediculated, others resembled venereal condylomata. The colour was always a rosy red. The nose was very much altered and deformed, rosy in colour, and glazed as if it had been varnished. The lower border of the septum and the free border of the nostrils were enlarged and excavated, looking not unlike lupus. The tumefaction was so great as to prevent the entrance of air into the nose. Many other parts of the body were similarly affected by the double process of vegetation and cicatrisation, and he describes his case as an "atrophic and vegetative form of iodine eruption."

Besnier's[12] patient was a male, aged forty, who took two grammes of iodine daily. At the end of a week he returned with the face and thorax covered with small rapidly growing true tumours, varying in size from a pea to a bean. They were coppery red in colour, soft to the touch, almost like a mushroom, and presented punctiform lacunæ analogous to those of an anthrax furuncle. From this resemblance he named it "anthracoïde." It was impossible to express any contents, and incision only gave exit to blood. The eruption was accompanied by burning pain, but there was no disturbance of the general health; and, indeed, the patient looked on the eruption as a favourable sign that his disease was "coming out." He had no idea that it was connected with the drug. On the cessation of the drug, and the application of glycerine of tannin, the eruption disappeared in a fortnight, leaving behind it small cicatricial depressions. Besnier remarks that this case can only be compared to those caused by bromide, and noted by Voisin.

E. Bradley,[13] in a very exhaustive account of other forms of iodine eruption, makes only a brief allusion to this form, saying that "the eruption can be papular, or consist of subcutaneous nodes analogous to erythema nodosum.

"In Pellizari's[14] first case — a syphilitic male, aged forty — there appeared, preceded by chills and fevers, a papular and rupiform eruption. The papules were few in number, almost level with the skin, not extending deeply, and not containing blood. They had a rough surface, and were of a dark strawberry-red colour, which only slightly disappeared on pressure. The bullous form was chiefly on the limbs. The bullæ averaged half an inch in diameter, and were similar to the bullæ of rupia, having a deep base surrounded by an areola. They were of a light-yellow colour. On opening the bulla no characteristic ulcer was seen at the base, which was, however, irregular and covered with small pieces of gangrenous-looking tissue, but hardly any bloody sero-pus was present. A third manifestation was in the form of subcutaneous nodes. There were three of these tumours, varying from a nut to an apple in size. One was soft and covered with healthy skin, another was surmounted by a large blister of a slatey-grey colour. Every fresh exhibition of the drug called out these same manifestations. He quotes, on the authority of his father, Pellizari, two cases where similar subcutaneous nodes were caused by the drug. His second case was that of a young prostitute, aged eighteen, who had been treated by her employer with large doses of iodide on account of a sore on her genitals. She was covered with numerous pasty nodules varying in size from a hazel nut to a walnut. They were painless, deep-seated, and covered with healthy skin. Only a few of the smaller ones were covered with a reddened cutis. These cases bear no very close relationship to the form we are at present discussing. I have related them because the papules and bullæ which occurred in Case 1 have most probably a relationship to the tuberous form. It will be noted that in their progress they correspond to the case described by Fox. The subcutaneous nodules, as will be seen on reading the pathological anatomy of our case, are in no way connected with such cases as ours.

Duhring[15] describes a case which he calls "local circumscribed phlegmonous dermatitis," due to the ingestion of iodide of potassium. A tumour arose on the forehead which grew to a size of two inches, and was not unlike ringworm in appearance. It was surrounded by vesicles, pustules, and nodes.

Taylor[16] records a case where, after very prolonged and

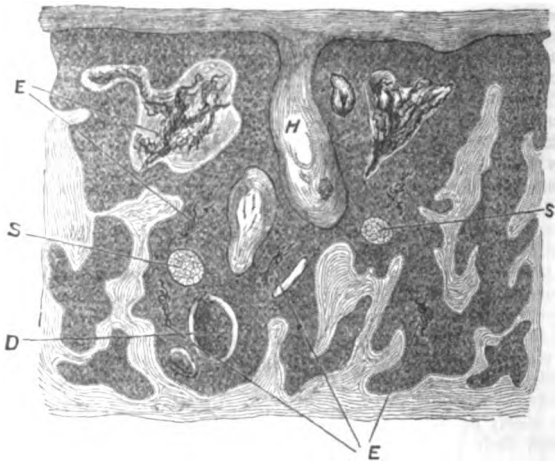
Digitized by Google

frequent dosing with iodine, the forehead, cheeks, eyelids, and neck became covered with a number of distinct tumours. They were deep red in colour, and varied in size from 0·5 to 15 mm. They were much larger on the surface than on the base, many having a mushroom-like form. They were very soft and yielding to the touch, and a little pus could be squeezed from some of them. The large ones had numerous little trumpet-shaped openings from which pus could be pressed. There was very little constitutional disturbance, and the tumours mostly disappeared in a week under the application of tincture of perchloride of iron. He considered the process one of inflammation of the sebaceous glands.



The date of the appearance of the tumours varies in different and also in the same cases. Pellizari, who verified his diagnosis by inducing the eruption several times, found the time necessary for its production varied from thirty-six hours to ten days. Duhring gives four hours, Hyde three days to three weeks, and in the case under consideration the first appearance of the tumour was five days after the first dose of iodide. It is an interesting fact that practically none of the patients showed any of the more common manifestation of iodism. Although iodine has been frequently demonstrated in the urine, as indeed it can be in that of anyone taking the drug, none of the previous observers have succeeded in demonstrating its presence in the lesion. In examining a portion of the tumour immediately after removal I was equally unsuccessful, but on testing the alcohol in which the greater part of the tumour (cut in small pieces) had been hardened for three weeks the hydrochloric acid and chloroform test showed a distinct violet tinge. Control tests were of course made, and gave absolutely negative results.

The anatomy of this form of eruption, or of forms nearly allied to it, has been described by Thin[17] from a case of Vincent Harris, Duckworth,[18] Hallopeau,[19] and Pellizari.[20] Thin found the blood and lymph vessels dilated, the latter filled with leucocytes. The normal (?) sebaceous glands in the neighbourhood were swollen and filled with disorganised blood. Dyce Duckworth describes his case as "localised superficial dermatitis." The hair-follicles and sweat glands were unaffected; the vessels numerous and sheathed with exudation corpuscles. The effusion was greatest in the papillary layer, which was flattened out and excavated. Hallopeau describes the histology of his case as a "dermatitis relatively recently developed, and especially in relation to the vessels." He says, however, that the papillæ are elongated, some filiform, and others very much swollen. The interpapillary processes of the rete are thickened, equally elongated, and larger than normal. Pellizari found dilatation of the sebaceous glands, which, as well as the vessels, were surrounded by a collection of round cells. From this presence of cells around the vessels he concluded that the cause of the disease had its seat in a special irritability of the vessels, and was a species of purpura.

Portions of our tumour were hardened in alcohol and Flemming's solution embedded in celloidin and paraffin, and stained by a large variety of methods. The first noticeable point on examining a section was the enormous epithelial growth, which at first sight gave one the impression that the section was that of an epithelial cancer. This, however, closer inspection removed, as the process was evidently an abnormal and excessive upward growth of all the skin elements, and not a downgrowth of the epithelium into the connective-tissue beneath.

Fig. 4 shows the appearance of a section under a low power, with the epithelium extending from the cut margin to the surface of the tumour. The fibrous tissue can be observed to be sharing in the new growth, but not by any means to the same extent as the epithelium, while the comparatively regular arrangement and relation of the two elements are also noteworthy. The epithelium is in a most active state of proliferation, sections stained with methyl blue or safranin showing everywhere numerous mitoses. The mitotic process was also observed in some of the connective-tissue cells. The elastic tissue does not appear to have shared in the abnormal activity of the new growth. Sections stained with orcein do indeed show that it is present; but it is only present in small amount, is distinctly thinner than normal, and is generally matted together in bundles or arranged like a tangled skein of thread. It has in all probability been carried from its original seat by the growth of the other tissues, and this is the more probable as in some instances fibres appear to be entirely surrounded by epithelial tissue. The bloodvessels are much dilated, their walls thin, and in some sections vessels of unusual size lie covered by little more than a layer of epithelium. (This superficial position of vessels is noted by Hallopeau.) The connective tissue everywhere is very œdematous, the capillaries and lymph spaces being largely dilated, and some of the spaces contain

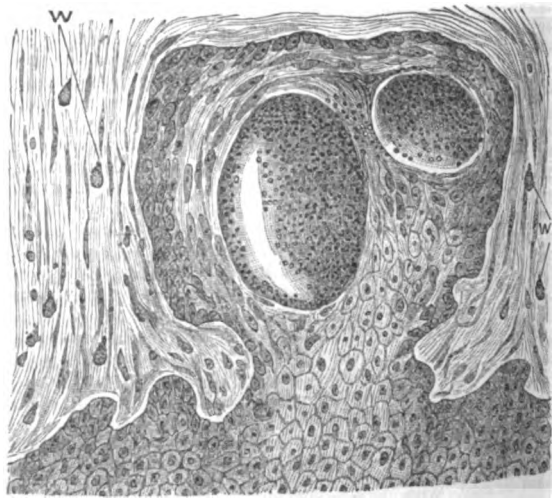


FIG. 4.

wandering cells. Methyl blue sections showed the presence in the connective tissue of a considerable number of "Mastzellen" stained of the usual purplish-red colour. As a rapid growth such as we are considering can hardly be put in the category of chronic inflammation, their presence is another proof that these curious bodies are not associated with that condition only. Nearly two hundred sections were carefully examined without finding anywhere a single trace of a sweat duct or gland; but in a few sections the concentric arrangement of

FIG. 5.

the epithelial cells on the side of a hair-follicle suggested the presence of a duct opening. The hair-follicles, which were found in considerable numbers, were, as usual in this situation, large in size. They were frequently filled with horny débris, among which varying numbers of pus cells could be seen. The number of micro-organisms found in the follicles was not greater than usual. They were in-

variably surrounded by an enormous growth of epithelium, and often in their immediate neighbourhood was a large or small collection of leucocytes. These collections were also found in other parts of the tumour, some of them covered only by the horny layer, and thus presumably forming those small yellow points which have been noted by many observers. Among the leucocytes could be seen the more or less perfect remains of flat, nucleated epithelial cells.

On a mere superficial examination the impression produced at first is that the sebaceous glands, at all events as such, do not exist in the tumour. Close inspection, however, shows here and there sections of two or three sebaceous cells surrounded by epithelial tissue, and in one or two sections larger portions can be seen. In considering the relation of these glands to the tumour there are two theories which have to be considered. One is that the excess of the tumour which was removed was above the level of these glands, and that the portions which can be seen are merely tangential sections of normal glands. This view, however, appears to me to be hardly tenable. Not only were portions

FIG. 6.

Sebaceous gland. The marginal cells are proliferating as epithelial, and not degenerating into sebaceous, cells. M, Mitosis. Z, Mastzellen. × 300.

of the tumour one-fifth of an inch thick cut entirely in sections, every one of which was mounted without showing anywhere a large section of gland, but the portions embedded in paraffin were mounted serially, and almost every section only showed the few sebaceous cells above referred to. The other, which seems to me to supply the key to the process, is that these cells are the remains of the normal sebaceous glands which are usually such large and striking features in a section of the skin from this region. The position of these cells in relation to the hair-follicles, the fact that they are invariably surrounded by large new growths of epithelium, and the large size of the normal gland in this region, seem to be sufficient evidence that the new growth of epithelium has taken place in relation to these glands. If the tumour were really removed above the level of the glands, it would seem to me impossible that almost every other section should show, on careful search, some trace of a gland. Tradition is not always a good guide in investigating histological relations, but it is at least a matter of interest that many observers have considered that the various lesions produced by iodine do have their seat in the sebaceous glands. Unfortunately, the process had in this case gone far, and it was therefore not possible to obtain a section showing the very earliest evidences of change; but one section, which taken alone would be of little value, when examined in the light thrown on it by those in which the process is further advanced, seems to give at all events a suggestion as to how the process commences. In the section referred to (Figs. 5 and 6) the gland lies much deeper than usual. It shows a section of a hair-follicle with sebaceous cells on each side. On one side the cells are entirely surrounded by proliferating epithelium, while on the other the gland can be analysed into three portions. Farthest from the follicle the new epithelium is invading the gland. In the centre we have the sebaceous cells, and immediately in relation to the follicle the gland has broken down, and the formation of pus has taken place.

The process would seem to be this: Owing in some way to stimulation by the iodine the epithelial cells lining the gland do not undergo their normal fatty degeneration and transformation into sebaceous cells; but, reverting under the stimulus to their primitive type, they proliferate once more as true epithelial cells. The sebaceous cells already existing merely fulfil their normal destiny, and as they break down and are thrown off into the follicle, their place being no longer filled by the development of new sebaceous cells, the number gets less and less, until we have the appearance shown in Fig. 6 of two or three sebaceous cells surrounded by a large mass of proliferating epithelium. The cells at the margin can be observed in a condition of active mitosis. The new formation is, however, not entirely confined to this seat. As to the relation of the sweat ducts, I was unable to make any direct observation. The epithelium was never distinctly observed descending from the upper layer, but that lining the hair-follicles, apparently also affected by the stimulus, proliferates rapidly, and sends out from the sides of the follicle buds of epithelium. To these buds is due the irregular growth in the upper part of the tumour, while the large masses lower down are occupying the position of the sebaceous glands. A degenerative process is, however, also present. In the hair-follicles, occasionally in the sebaceous remains, and often also in the centre of epithelial masses, leucocytes have found their way and led to the formation of small abscesses, the existence of which has been frequently noted clinically.

In conclusion, I must tender my thanks to Dr. Unna, firstly for his kindness in entrusting me with the investigation of the case, and secondly for his help in elucidating doubtful points; and also to Dr. Phillipson of Hamburg for his most useful, if at times adverse, criticism.

Edinburgh.

MORBUS COXÆ.

WITH DESCRIPTION OF A NEW BED.

BY E. STANMORE BISHOP, F.R.C.S. ENG.,
HONORARY SURGEON TO THE ANCOATS HOSPITAL, MANCHESTER.

THE problems which any surgeon has to face, when called upon to treat a case of morbus coxæ, will vary greatly. In some the tendency to recovery, as Thomas of Liverpool used to say, is so great that mere protection from further harm is all that is necessary. The patient has a good family history, is in every other way in good health, until the fall or other accident happened which produced the synovitis or osteitis. A short rest, protection against repetition of the injury, and some slight medication, and the boy is as well as ever. Varying combinations of injury and constitution produce varying results of lighter and graver kind, the character of the constitution appearing to have the strongest influence in the modification; more and more difficult becomes the struggle for recovery, until in some extremely strumous children the merest knock or tumble appears sufficient to light up a persistently progressive disease which ends in death or permanent and very marked lameness. Of course, the measures required must equally vary. In the lighter cases the most that is required will be a light Thomas's splint, with patten and crutches. The little patient can go about almost from the first. He can benefit by fresh air and a slight amount of exercise. There is never a hint at suppuration, and bedsores are not dreamed of; therefore all through its duration there has been nothing extraneous to lower the vitality or decrease the chances of recovery. But it is far otherwise with the more delicate cases. It is another exemplification of the old text: "To him that hath shall be given, but from him that hath not shall be taken away even that which he seemeth to have."

From the first the often comparatively slight injury has acted like a spark amongst shavings. Rapidly the inflammation increases; every slight movement gives great pain, and causes fresh and increased irritation. The little patient is racked with the constant suffering, and weakened by the feverish reaction. It is imperative that the joint shall rest, and that absolutely, but the skin is so sensitive and so lowly vitalised that continual rest in bed

Digitized by Google

produces bedsores, and the pressure of an iron splint is unbearable. Moreover, to children of this age perfect rest in one position is the acutest misery. But if this is bad, the next stage is infinitely worse. A large abscess forms in or around the joint, with disintegration of the femoral head or the acetabulum, or both. It is necessary to remove the necrotic or carious bone, and to provide free exit for the abundant pus. At the same time it is imperative that the large cavity produced should be kept aseptic, or septic fever or pyæmia will certainly carry off the patient, already so greatly enfeebled. But the opening which has to be made is at the very centre of the body, and close to the two main emunctories, and the dressing of the wound is painful, and almost necessitates the lifting of the patient, when movements at the very spot which should be most immovable will certainly take place. Sooner than call attention to himself and risk the repetition of the dreaded dressing, the child will lie with its excretions soaking into the coverings of the wound; and it requires the most careful nursing to prevent this. Careful nursing may, and doubtless will, do much to obviate the danger; but it cannot prevent the pain endured at every dressing or cleaning, nor the ever-recurrent dread in which the life of the child is passed at this time, when of all others, for the best chance of its recovery, its mind should be at ease. And to add to all this, one of the best helps to the child's recovery is fresh air, and this is almost, if not quite, unobtainable. To dress the wound sufficiently often to secure asepsis without pain or movement at the diseased part, to permit of the performance of the natural functions without danger of soakage of decomposable or decomposed material into the cavity produced by operation, to keep the bones of the trunk and lower limb in their relative position whilst permitting the area of pressure to be varied from time to time, or even, if possible, occasionally allowing the patient the upright position—these are the problems which every surgeon tries to solve who has to treat one of these severe examples of morbus coxæ. And the appliances at present in use do not assist him greatly. Some—most—are effective only so long as the patient lies supine, the bed itself forming an integral part of them; so that the difficulties arising from decubitus are not to be thus overcome. Some are too heavy, and some must be removed at the time when they are most required, during the change of dressings. To assist in solving the difficulty I have devised a bed which is pivoted, the pivots at each end resting upon upright standards, which with the framework beneath form its support and hold it at a convenient height from the ground, so that the patient shall be on a level coincident with the surgeon's chest. When the child is laid supine, its chest is comfortably held by flexible bands, which are fixed below to the bed itself and united in pairs above. Its legs lie each in a separate channel, which is suitably padded. The sound extremity has its foot firmly braced against a wooden block, which can be fixed at any point, whilst the affected limb has an extension apparatus applied, the cord of which passes through an eyelet on the lower arc, and is connected with a weight, which acts in any position of the bed. The hips rest each upon a pair of trap-doors which open downwards, and allow free access to this part of the body. The traps beneath the sound hip are always bolted, and maintain, in conjunction with the extension, the body and diseased limb always in the same plane, whilst the unsound region can be reached with comfort, dressed or cleaned with ease, and without discomfort to the patient.

As the bed is pivoted, it is easy to see that it is capable of alterations in position so that the plane of pressure can be constantly varied. This is usually done by turning the bed so that one of the perforations in the upper pivot coincides with one of those in the standard, and fixing it at that angle by a steel pin; but if greater range of movement is required, a worm-and-wheel movement is attached, which renders it practically unlimited. In any case, there is no alteration in the relative position of parts operated upon, as the whole body is moved at one time. When the case is sufficiently advanced to permit of the upright position, the lower arc and the extension can be removed, and the entire bed placed against the wall in an almost vertical position. The patient then resting his sound foot on the block, and secured to the bed by the chest and hip bands, has extension going on by the weight of the unsound leg, and is in practically the same condition as if he had a Thomas's splint and patten applied. Several severe cases have been treated by its means in the Ancoats Hospital, and in every instance with success, whilst the comfort to nurses and surgeon, and the freedom from the distressing scenes formerly so common, have been most marked. But whilst this bed was originally intended for the treatment of severe morbus coxa, it is extremely useful for other purposes, such as the treatment of fractures of the lower extremity, and for any case in which the supine position has to be maintained for any length of time.

These beds are now made by John Carter, 6A, New Cavendish-street, Portland-place, W.

Manchester.

LARYNGEAL CHOREA.

By JAS. H. NICOLL, M.B.,

SURGEON TO OUT-PATIENTS, GLASGOW WESTERN INFIRMARY, ETC.

By the term "laryngeal chorea" is here meant an affection of the laryngeal muscles similar to that of the other muscles of the body in the disease commonly described as chorea. Under the term "laryngeal chorea," or "chorea of the larynx," certain authors have described an affection of the laryngeal muscular system resulting in certain defects in vocalisation. The descriptions of its symptoms and causation are almost as varied as the authors referring to it are numerous. It would seem to be in some respects analogous to "writer's cramp,"—i.e., a fatigue or spasm of certain of the laryngeal muscles, and the latest view of its causation seeks to trace it to a faulty habit of voice production from an inability to breathe during sustained speech or song. The term "vocal asynergy" has been given to it, and, both for the sake of distinction and because the term seems more accurately descriptive, it would be well to use it alone.

That the laryngeal muscles are liable, in common with all the muscles of the body, to suffer in chorea and to exhibit the movements characteristic of that disease is well known. Ziemssen and other authors have described such movements of the laryngeal and respiratory muscles, with resulting irregularities in speech and respiration and the production of unexpected "grunting" noises in the throat. During the past four years there have come under my observation three cases of chorea commencing in the pharyngeal and laryngeal muscles, and limited for some considerable time to these muscles, the only symptom being a cough. As these cases, in the first place, presented very considerable difficulty in diagnosis, and, in the second place, are of a class to which I have been able to find only one distinct reference in the more accessible literature of chorea, and as, finally, they came under my notice accidentally, I feel constrained to give them publicity in order that the value of the observations made, and the conclusions drawn therefrom, may be tested by those who, from the nature of their practice, have more ample means of observation of choreic patients and of laryngeal disorders. That such cases are fairly common seems probable, unless one is to conclude that my experience has been altogether exceptional. That the true diagnosis of the laryngeal affection, as evidenced by the cough, is frequently missed seems still more probable, seeing that a laryngoscopic examination is necessary to establish it, such an examination being by no means of easy accomplishment in children, the usual victims of chorea. In Case 1 the correctness of the diagnosis may be questioned, but as it was the means of directing inquiry in the second and third cases I give it here along with them.

CASE 1.—J. H——, aged eight. This boy is the son of a lay friend in Glasgow. Four years ago, when house surgeon in Glasgow, and visiting frequently at my friend's house, my attention was directed by the parents to the boy's condition, which was giving them some anxiety. At that time he was a healthy well grown child of nearly four, and had had measles only of the usual troubles of childhood. There was neither family nor personal history of rheumatism or any "neurosis," nor had he suffered from fright or shock. For several months he had been troubled with a cough, which distressed both himself and his parents, and for which he had been unsuccessfully treated by several practitioners. The cough, which at first had recurred at intervals of hours, had gradually increased in frequency of repetition to intervals

Digitized by Google

of only a few minutes towards night, though in the early part of the day the intervals were more prolonged. It always ceased during sleep, though not infrequently preventing sleep for a time after the child was put to bed. I did not see the child professionally, and therefore did not examine him in any way, but the characteristics of the cough were unusual in a child, and attracted my attention. Nasal respiration was free, and there was no abnormal respiratory sound. The cough was invariably of the same type. It was not the hoarse or aphonic cough of laryngeal inflammation or growth, nor the noisy "moist" rattling or wheezing cough of bronchitis. It had not the prolonged paroxysms and inspiratory crow of pertussis, nor the "hawking," "hemming" character of the cough due to the effort to clear secretion from the pharynx. It consisted in a sudden single sharp dry cough, like that produced in adults by the sharp contact of a probe with the external auditory meatus near the tympanic membrane. It appeared, in short, to be the cough of momentary irritation of some spot capable of reflexly exciting the cough centre. The cough persisted, gradually increasing in frequency, for ten months, when typical choreic movements appeared in the legs, gradually extending over the entire body, with great increase in the severity of the cough, which became still more frequent and of a hoarser quality. The attack of general chorea lasted over one year, was treated by bromides, and since its cessation has not returned. The cough diminished with the other symptoms, its final cessation preceding that of the limb movements by several weeks.

CASE 2.—J. S——, aged fourteen, came under my observation at the Public Dispensary in Stoke Newington, London, in November, 1889. He complained of a troublesome, "hacking cough." The characters of the cough were such as to at once recall to my mind the case of my friends' child (Case 1). The description of the one cough exactly describes the other, with the exception that J. S——'s mother stated that he frequently coughed during the night. He had had scarlet fever and measles before the age of four. One uncle had chorea in youth. Beyond this there was no history, personal or family, of rheumatism or nervous affection. He was a stunted, thin boy for his years, but was said to enjoy good health. The cough had troubled him for several weeks, and occurred at intervals of two or three minutes. Respiration was normal, and there was slight hoarseness. His lungs and heart, on examination, appeared healthy. On completely stripping him, no muscular tremor or twitch could be detected in any part. Physical examination of ears and nose detected nothing abnormal, and the mucous membrane of the pharynx and mouth was healthy. The tongue was absolutely free from abnormal movement, but the soft palate exhibited frequent twitchings of momentary duration. Laryngoscopically the ventricular bands seemed of a deeper hue than normal. The vocal cords, while in energetic normal motion, as in phonation and deep inspiration, acted readily and fairly steadily; but when relieved from conscious voluntary effort, and left to the more passive movements of quiet respiration alone, they exhibited frequent jerky movements of unequal extent towards and away from the middle line. So far as could be observed, the two cords were equally affected, and moved simultaneously in all such movements with one exception. Near the junction of the posterior third with the anterior two-thirds of the right cord there was a darkish red area. At intervals the right cord exhibited a movement by which it became partially kinked, the apex of the kink, which was convex outwards, being situated at the red part. (Such a movement in a vocal cord is something unique, in at least my experience, and its causation opens a wide field for speculation. The only thing approaching it I have met was a case I observed over two years ago, when assistant to the Central London Throat Hospital, in which an elderly man came complaining of his voice "going off in squeaks." In his case, on attempting phonation for low notes, both of his cords were observed, just after sound production had commenced, to suddenly leave the middle line and jerk outwards, momentarily forming sharp curves with the convexity outwards. In this case both cords were bent or curved and the position was less of a sharp kink than was the case in my choreic patient, in whom the kink in the right cord was a more or less angular one, the apex corresponding with, and presumably causing, the small congested area. As to the mechanism by which such a position of the cord became possible, adductor paralysis, which in its early stage at least gives rise to an outward bend during deep inspiration, may be dismissed. The bend was too acute and too transitory, and there was no other evidence of paralysis. It is open to assume either, on the one hand, a sudden spasm of the whole or of a part of the thyro-arytenoid muscle of the affected side; or, on the other, what seems more probable, some sudden tilting or shifting of the thyroid cartilage by the intrinsic or extrinsic muscles, causing some alteration in its relations to the cricoid other than that normally produced by the action of the crico-thyroid muscles—a partial dislocation, in fact, or sliding of the inferior cornu of the thyroid on the flat articular surface of the cricoid.) The larynx as a whole appeared not to be shifted in position by any choreic spasm of the external muscles attached to it, and, indeed, except in the palate and intrinsic laryngeal muscles, no choreic movements could be detected. The cough exhibited all the reflex associated muscular action normal to such an act, the contemporaneous fixing of the muscles of the neck and the diaphragm, the contraction of the chest and the explosive passage of air through the rima glottidis denoting a physiological combination of forces to effect one object, strongly contrasting with the irregular and apparently purposeless choreic laryngeal movements. On the patient's second visit a week later, in order to obtain a more complete examination, the fauces and pharynx were painted and the larynx sprayed with a 5 per cent. solution of cocaine. (N.B. Much of the information detailed above as to laryngeal movements in this case was obtained at the second and subsequent examinations under cocaine.) Within a few minutes after the application the cough had entirely ceased. The choreic movements were quite unaffected. The application of cocaine was repeatedly made within the next few weeks, and invariably with the same result—viz., the complete cessation of the cough, the choreic movements continuing unaffected. On several occasions when no cocaine had been employed I probed different points of the pharynx and larynx, and in particular the congested spot on the right cord, in order to discover, if possible, a reflex spot which might excite the cough. I failed to do so, but cannot regard the result as of any conclusive value, as, in in the first place, I easily excited retching in the pharynx; and secondly, the congested spot, which might reasonably be supposed to be the cause of the cough, was not easily hit, owing to the choreic movements. The patient was treated with chloral and bromides. Five weeks after his first admission a slight twitching in both coraco-brachiales was detected. Shortly after the hands and neck became affected, and subsequently the whole of the upper limbs. The choreic attack was a mild one, and the patient was dismissed well nearly four months after the arms were affected, the laryngeal symptoms being the last to subside. The cough ceased with the laryngeal movements, having survived by six weeks the red congested spot, which disappeared on the commencement of the subsidence of the muscular twitchings.

CASE 3.—A. P——, aged fifteen, was admitted to the Public Dispensary, Stoke Newington, London, in the spring of last year complaining of a "dry cough." The patient was a healthy-looking well-grown girl approaching puberty. She had never menstruated, had had one previous attack of chorea, and there was a family history of both chorea and rheumatism. The characters of the cough were similar to those in Case 1. On stripping the patient slight but distinct choreic movements were seen in the forearms and fingers. The tongue was slightly affected, but no movements of the palate could be detected. On laryngoscopic examination irregular movements of the cords towards the middle line were seen to occur frequently. Occasionally one cord appeared to move independently of the other, or, at least, to precede the other in movement, but the motions were so rapid and irregular that accurate observation on this point was impossible. The larynx as a whole was frequently raised and depressed by the extrinsic muscles acting on it, which were also to a certain extent affected by choreic spasm. The mucous membrane of the larynx and pharynx seemed perfectly healthy. Nothing abnormal was found in nose or ears, and the lungs and heart appeared to be normal. The pharynx and larynx were sprayed by cocaine on several occasions, but without any such result as followed the application in Case 2. Both cough and muscular movements remained unaffected. The cough, which occurred at intervals of three or four minutes as a rule, occasionally recurred more frequently, so that during a period of from six to ten seconds four to ten coughs

Digitized by Google

might occur. Such periods of greater frequency were of very irregular occurrence, and repeated observation convinced me that their commencement coincided with alterations in position of the whole larynx by the extrinsic muscles, and that the alterations with which they were associated were those in a downward direction. Descent of the larynx was, though by no means invariably, frequently the starting-point of one of these periods of frequency. That it was the cause of these periods was difficult of proof; for while ascent, which was easily produced voluntarily in swallowing, failed to produce increased frequency or to excite the cough in any way, descent to any great extent could not be produced at will, that connected with the production of deep notes being insignificant in extent in comparison with the ascent of deglutition. The amount of descent produced in this patient, however, by choreic spasm of the depressors of the larynx appeared to be all but, if not quite, as great as the amount of ascent. In order to test the point as far as possible, having placed the patient recumbent with her head hanging well back over a pillow under the neck, I grasped the larynx, and, pressing it well up towards the base of the tongue, held it there as steadily as possible. This manœuvre, which I repeated on several occasions, never failed to check all cough for a period which varied from twelve minutes to twenty-eight minutes on different occasions, but on all these occasions cough did return before the larynx was released from its fixed position. During fixation of the larynx in such a position laryngoscopic examination was of course impossible, but the movements of the tongue and of the depressors of the larynx continued.

Dr. B. Sachs of New York, writing in the "Encyclopædia of Diseases of Children," says: "Laryngeal chorea is a special form of chorea in which the laryngeal muscles are chiefly affected, the result being a peculiar bark which is repeated at short intervals. These cases are sometimes mistaken for cases of hysterical bark, but the general restlessness, the age of the patient, and the choreic movements of the tongue make the diagnosis an easy one. From my own experience I infer that this is the rarest form of chorea." This, as I have said, is the only distinct reference to such cases as the above which I have been able to find in the more accessible descriptions of chorea and laryngeal neuroses, and it may be of interest briefly to examine the cases and Dr. Sachs' description a little more in detail. In regard to Cases 2 and 3 it seems to be reasonable to conclude that the cough was the result of chorea of the laryngeal muscles. Case 1, though very suggestive, has not, for obvious reasons, the same claim. In regard to the ease of diagnosis, I cannot agree with Dr. Sachs. Certainly in Case 3, where there was neither "general restlessness" nor "choreic movements of the tongue," nothing but a laryngoscopic examination could have established a diagnosis, at least for many weeks. Into the interesting question of the mechanism by which the cough was produced in these cases, others with more ample means of observation will be able to enter. Dr. Sachs says: "The laryngeal muscles (*vide supra*) are chiefly affected, the result being a peculiar bark &c.," just as, presumably in the same way, in chorea of the forearm the flexors and extensors of the fingers are affected, the result being movements of the fingers. It seems needless to point out that a cough is a purposive act comprising many complicated muscular efforts coördinated into one whole, which is set in action by a reflex excitation or by voluntary effort. Such an act is quite unlike the irregular faulty spasmodic muscular movements of chorea which, when occurring in the larynx or pharynx, may, by obstructing the current of air in a more or less passive and accidental way, cause irregular speech or respiration, or even unusual laryngeal sounds—indeed, a cough could not be produced by any action of the laryngeal muscles alone. The facts of the above cases seem to point to the conclusion that the reflex cough was excited by abnormal sensations in the larynx caused by the choreic movements of the muscles. The cessation of the cough under cocaine in Case 2 seems to demonstrate this, for in this case the only abnormal condition found beyond the choreic movements was the congestive spot, which disappeared six weeks before the cough. Further, cough from such irritation as inflammation or congestion of the laryngeal mucous membrane would hardly exhibit such characters as were observed in these cases, but would be more prolonged and paroxysmal, and would almost certainly be accompanied by hoarseness and aphonia, from an early period of its duration. Hoarseness at a late period of chorea of the larynx may accompany the cough. This occurred in Case 1, and was probably due to some amount of congestion or inflammation of the laryngeal mucous membrane due to the irritation of the continued cough. The momentary choreic contractions of the muscles would, in all probability, cause unexpected tensions and bulgings, or possibly contacts of various points of a very sensitive mucous membrane, irritation of which invariably leads to cough. The sensations produced in this way would, it may be supposed, simulate closely those due to momentary contact of a foreign body. That in Case 3 cocaine had no effect in checking the sensibility of the membrane and thus stopping the cough is no argument against this view. Stoerck of Vienna and other observers have proved experimentally that cough may be excited by irritating by contact the mucous membrane over the inter arytenoid folds, the posterior wall of the larynx, and the upper surface of the vocal cords, and also the inferior surface of the cords and the trachea, especially its posterior wall, for some distance below the larynx. It requires no argument to prove that the application of cocaine, even by the spray, to the inferior surface of the cords and the larynx and trachea below the rima must be a thing of so great difficulty that its possibility is very doubtful. Therefore, should the point irritated by the choreic movements be below the rima, it is not to be expected that the application of cocaine would check the reflex. Now in Case 3 there was (*vide supra*) some reason to think that the starting point of the reflex was below the rima, for it was just when the larynx descended, and possibly caused some pressure on or folding of some part of the mucous membrane below the cords, that cough was excited or increased. Though experimental demonstration of this was impossible, some negative evidence in proof of it was obtained by holding the larynx well up under the base of the tongue and jaw as described. This was always successful for a time, but it is open to anyone to argue that tightly grasping the throat would tend for a time to check cough arising from any cause whatever, and that the return of the cough, when presumably the parts had become accustomed to the manual pressure, demonstrates this. My own impression is that the amount of compression used was not sufficient to support this argument, and that the true explanation is that by preventing descent of the larynx the source of irritation was removed, the ultimate return of the cough being due to one of two causes, either a momentary or gradual relaxation of the restraint on my own part, or an unobserved and gradual movement of the patient to relieve an irksome position by bringing the rest of the body up to the raised larynx, as the larynx could not descend to the body, the effect in either case being the same.

Glasgow.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

RUPTURED HEART.

BY BARRINGTON WM. MUDD, M.B., C.M.ABERD.

AS rupture of the heart is a lesion of somewhat rare occurrence, the following case may be of some interest.

J. W——, aged thirty-one, carman, was brought to me a few days ago, having been found lying on his face at his horse's feet quite unconscious. He had been seen a minute or two previously standing at the heads of the horses, ready to back his van into a shed. The men who brought him said they thought the pole of the van must have struck him on the chest, but of course this was mere supposition, as nobody had seen him fall. On admission, half an hour after being picked up, I found him quite unconscious, voluntary motion being absent. He was extremely blanched; pupils widely dilated, and showed no reaction to light; pulse hardly perceptible; perspiration profuse. In this condition he remained for nearly an hour when he began to show signs of slight consciousness. I asked him if he had any pain; he understood me, and put his hand to his chest. About a quarter

Digitized by Google

of an hour later he vomited a little blood, and expired shortly afterwards. He lived two hours from the time he was picked up.

Necropsy.—Externally there was a slight abrasion over the centre of the sternum; with this exception there were no other injuries on the body. On opening the chest the pericardium was distended, and on opening it I found it contained a quantity of uncoagulated blood. This I carefully removed, and then I could see that blood was oozing from the right auricle. On further examination I found that there was a laceration situated just between the auricular appendix and the commencement of the superior vena cava, measuring in length about a quarter of an inch and an eighth in breadth. The heart was slightly undersized and its muscular tissue was pale, while on the surface there was an undue amount of fatty deposit. This case, I have no doubt, was traumatic, although there is very little to prove it. With the exception of the abrasion over the sternum there were no other signs of injury. I am inclined to think that the condition of the heart predisposed to the lesion, as the accident which caused it could not have been severe, otherwise there would have been more contusion and injury to external structures.

Seamen's (Branch) Hospital, Albert Docks, E.

DIPHTHERIA ARISING FROM FAULTY DRAINAGE.

By H. MALLINS, M B.

THE remarks in THE LANCET of Feb. 20th, under the heading of "Insanitary Dwellings," leads me to briefly place on record an unequivocal case of the origin of diphtheria from faulty drainage, which came under my observation some five or six years ago. The case was that of a boy ten years of age, who was attacked with membranous sore-throat, followed in a few weeks by almost universal paralysis, a circumstance that proved its true diphtheritic nature. On endeavouring to trace the source of infection I found that the bed in which the boy slept was in a small room directly over the scullery, and that a most unpleasant smell had been noticed to pervade this room for weeks past. On examining the scullery sink it was found to communicate by an untrapped—in places broken—pipe with a cesspit situated about twenty-five yards from the house. There was, therefore, every opportunity for the foul air from the cesspit to be syphoned into the house. The patient was carefully isolated, and though one of a very large family of children no one else caught the infection. As there was not a single case of the disease in the neighbourhood, as the boy did not mix with any children except his own brothers and sisters, and, lastly, as he was the only one in the family sleeping in the line of escape of foul air, the conclusion seems irresistible that in this case, at all events, the diphtheritic poison was conveyed in the emanations from a foul drain, such emanations polluting the air that was nightly breathed. How the specific bacillus got into the cesspit is of course a very difficult matter to explain.

Watton.

CASE OF SYNCOPE DURING ETHER INHALATION.[1]

By A. C. WILSON, M.B., CH.B. VICT., &c.,
ASSISTANT HOUSE SURGEON AT THE SHEFFIELD GENERAL INFIRMARY.

THE following is an account of a case exhibiting grave and somewhat unusual symptoms while under the influence of ether.

A youth aged seventeen was admitted to the infirmary on Jan. 9th for a wound of the eyeball. He was well grown and free from any organic disease. Mr. Snell decided to enucleate the eye, and on Jan. 15th I administered ether in the usual way with Clover's inhaler. The patient took the anæsthetic extremely well, and was soon properly under its influence, as evidenced by the regular stertorous breathing, loss of corneal reflex, and contracted pupil. The ether apparatus was then removed, and Mr. Snell commenced the operation, but no sooner had he clipped round the conjunctiva and divided one of the tendons when suddenly the face and lips of the patient, up to this point of a good colour, became very pale. For a few seconds I thought he was going to vomit, but as there were no further signs of this, and as the breathing became sighing in character, and the pulse, previously full and regular, began to run rapidly down, the operation was at once stopped. We inverted the patient, drew forward his tongue, began artificial respiration and had the window opened. After doing artificial respiration for a few times we stopped for a moment to see if there were any response, but there was no breathing perceptible, and the pulse at the wrist was flickering. Artificial respiration was then resumed, flagellation resorted to, and the battery held in readiness. After some minutes the pulse improved, the patient was found to be breathing again, and he finally recovered completely.

A few points I wish to draw attention to: 1. The room was a small one, leading off from a larger one, and the air of both of these was, I think, exhausted by numerous outpatients. 2. The inhaler had been removed for quite one minute before the bad symptoms came on. 3 The extreme pallor the patient exhibited when at his worst. 4. His complete recovery. So far I have been unable to find any record of death from syncope during the administration of ether. Of eighteen deaths recorded under ether, the fatal result was due to asphyxia. How to explain the symptoms in my case appears difficult. Had the division of tendons of the eyeball anything to do with it? Mr. Mills, anæsthetist at St. Bartholomew's Hospital, speaking of syncope from chloroform, says: "This shock is very marked when, in the operation for strabismus, the internal rectus is divided, the pulse often intermitting and remaining feeble for some minutes." Now, if this operation has a lowering effect on the heart during chloroform anæsthesia, is it not possible that there is a similar tendency while under ether? It is true that there is some doubt as to whether it was the internal or the inferior rectus which was divided; but, since they are supplied by the same nerve, it can, I think, make little or no difference. On the other hand, the syncope may have had no connexion with the operation; and it is on these points that I should feel grateful for any suggestions from more experienced members of the profession.

Addendum.—Since writing the above I find that there are two cases of failure of the heart's action during ether inhalation recorded—one, in THE LANCET of October, 1876, by Mr. A. S. Morton; and the other, in the *British Medical Journal* of May, 1877, by Mr. R J. Pye-Smith. Doubtless other instances have been observed.

Sheffield.

ST. PANCRAS INFIRMARY.

A CASE OF SCIRRHOUS CANCER OF THE HEART.

(Under the care of Mr. C. DUDLEY COOPER and Mr. A. B. KINGSFORD, Assistant Medical Officers.)

DISEASE of the muscular walls of the heart of malignant nature is probably always of secondary character, and is of rare occurrence. Dr. Bristowe[1] writes: "Malignant disease of the heart and pericardium has rarely, if ever, been diagnosed during life, and, indeed, only gives evidence of its presence by symptoms referable to the heart. It is obvious, however, that the symptoms to be looked for are those indicative of cardiac obstruction and weakness, and that the supervention of such symptoms in the progress of malignant disease might suggest the possibility of cardiac

[1] The Theory and Practice of Medicine

Digitized by Google

involvement." In this case the absence of evidence of growth of any kind, primary or secondary, until the post-mortem revealed its presence, rendered diagnosis quite impossible.

George T——, a coach trimmer, aged forty-eight, was admitted into St. Pancras Infirmary on Dec. 7th in a semi-unconscious state, with a history of having been seized with right-sided paralysis and loss of speech on Dec. 4th. On examination of the heart the sounds were distant but distinctly heard, fairly normal in quality and regular in rhythm; the impulse was weak but not displaced, and the area of cardiac dulness was not increased. The patient improved slightly until Dec. 12th, when at 9 A.M. he suddenly became much worse; his temperature rose in a few hours to 107° F., and he died the same evening.

Necropsy.—On examination of the brain no hæmorrhages or emboli were found anywhere, but the left optic thalamus was decidedly softened as compared with that on the opposite side. On removal of the sternum several nodules were noticed on the surface of the heart showing through the pericardium, which, though completely adherent, was not involved in the growth. The ventricular walls were slightly hypertrophied, but the valves appeared perfectly normal. The chief seat of the growth was in the auricles; there were also several small masses about the apex, mostly involving only the outer half of the thickness of the (ventricular) wall, and nowhere projecting into the cavity of the ventricle. The endocardium of the auricles also was intact throughout; but outside this the walls of the left auricle were almost entirely formed by new growth, and attained a maximum thickness of one inch and a half. There were two masses of growth in the inter-auricular septum about the size of small filberts. The anterior wall of the right auricle also was almost entirely replaced by new growth, which extended thence up the adjacent wall of the pulmonary artery, embracing it so closely that it could not be dissected off. Several of the mediastinal glands were hard and enlarged. On examining the lungs, the left bronchus was found to be all but occluded by a mass of new growth close to its bifurcation, which was continuous with that in the walls of the auricle, and extended for a short distance into the tissues of the lung at its root. There were also a few isolated nodules of growth in the lower lobe of the lung. The masses of growth were white, hard on section, cupped slightly, and when scraped yielded a thin semi-transparent juice. On microscopical examination they were seen to consist of a large amount of fibrous tissue enclosing alveoli of various sizes. The alveoli contained many epithelial cells, some of which were distinctly columnar in form. A careful examination of every other organ of the body was made, and in none was any trace of growth found. Hence it was thought that the growth might have originated in the epithelial lining of some mucous gland in the left bronchus and have affected the heart and mediastinal glands secondarily. The case is of interest on account of the rare occurrence of the disease and the total absence of any symptoms pointing to so serious an affection of the heart and lungs.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

HYDRONEPHROSIS OF RIGHT KIDNEY; NEPHROTOMY; PYONEPHROSIS OF LEFT KIDNEY; NEPHRECTOMY.

(Under the care of Mr. WHIPPLE.)

THE explanation of this case seems to be as follows: The girl was the subject of some congenital stricture of both ureters. The left kidney first became dilated, and eventually all its secreting tissue was completely absorbed. Whilst the left kidney was undergoing atrophy the right kidney was undergoing compensatory hypertrophy, and at the same time its pelvis and calyces were dilating. At the age of fourteen the right hydronephrosis had become apparent. Ten years later the right loin being drained and all the urine escaping from it, it became evident that the left kidney was destroyed. The patient being very anxious to get rid of the fistula, an attempt was made, by exploring the bladder and the right kidney, to find the cause of the obstruction, which at that time was unexplained. Either owing to the examination of the bladder or the palpation of the left loin, suppuration was set up in the sac of the old hydronephrosis on the left side. For the notes of this case we are indebted to Mr. W. Gifford Nash, late house surgeon.

A. S——, aged twenty-five, a school teacher, was admitted into the South Devon Hospital on Nov. 18th, 1890, suffering from a renal fistula, of which she wished to be relieved. She stated that since the age of fourteen she suffered from a dragging pain in the right loin and occasional attacks of vomiting; she never had any hæmaturia or passed gravel. For many years she passed very little urine by day, but had to get up two or three times each night. On Feb. 19th, 1890, she was admitted into the West Kent General Hospital, Maidstone, where it was found that there was a large fluctuating swelling in the right loin. The circumference of the abdomen varied from thirty-two to thirty-four inches. The urine had a sp. gr. of 1010, and contained pus and phosphates. The daily quantity varied from sixty to 106 ounces, about two-thirds of this being passed by night. This ratio was maintained whether she got up or remained in bed all day. Under chloroform no urine could be squeezed from the tumour into the bladder. Nephrotomy was performed and 100 ounces of alkaline fluid containing pus, sp. gr. 1012, evacuated. A urinary fistula has remained since then.

On admission the patient was a florid and well-nourished woman, with a urinary fistula in the right loin just above the iliac crest. In the right loin and iliac region could be felt a large firm tumour. A probe passed into the fistula towards the umbilicus six inches, and upwards and downwards four inches each. No kidney could be felt on the left side. During the first week in hospital the urine from the loin averaged fifty ounces, but none came from the bladder. On Nov. 26th chloroform was given and the bladder examined digitally, but nothing abnormal was detected. The renal tumour was explored through the fistula, and the dilated kidney pelvis examined. The upper opening of the ureter could not be found. On Dec. 16th the patient had a rigor and aching in the left loin; next day two ounces of purulent fluid came away from the bladder. The signs of suppuration continued until operation. On Dec. 24th a swelling was first felt in the position of the left kidney, and on the 27th a pyonephrosis was opened in the left loin, and thirty-one ounces of pus evacuated. The sac was well washed out, and its edges stitched to the skin. After this there was no discharge of pus from the bladder, and the wound in the left loin rapidly contracted. On Feb. 13th, 1891, the wound in the left loin was enlarged, and the pyonephrotic sac peeled off the surrounding tissues, and as much as possible removed. The sac extended high up under the ribs, so that its upper part could not be got at. Nothing was seen of the remains of ureter or renal vessels. On July 24th, as there was still some discharge from a sinus running up under the ribs, chloroform was given and the cavity scraped out. A few days later there was a discharge of pus from the wound resembling softened spleen. This lasted three or four days, and then the discharge gradually diminished, so that when the patient left the hospital at the beginning of October there was only a small sinus remaining. The urine from the right loin contained about one-twelfth albumen, and was collected in a Maw's urinal.

Remarks by Mr. W. GIFFORD NASH.—The points in favour of the obstruction being a congenital stricture of both ureters, either at their origin from the pelvis of the kidney or at their entrance into the bladder, are the facts—(1) That the majority of hydronephroses in children are due to congenital narrowing at one or other of the spots mentioned, as shown by the examination of museum specimens; (2) the absence of any urethral obstruction or tumour of the bladder blocking the urethra, or involving the apertures of the ureters; (3) the absence of any history or signs of a previous attack of pelvic cellulitis; (4) the absence of any pelvic tumour; (5) the absence of history of renal calculi, or any other known cause of hydronephrosis. The other points of interest in the case are: (*a*) The increased flow of urine by night, which cannot be explained on mechanical grounds, as it occurred if the patient was up all day, or if kept in bed. (*b*) The large quantity and low specific gravity of the urine and albuminuria are no doubt due to the chronic interstitial nephritis which accompanies the hydronephrosis. (*c*) The escape of splenic pus, which is easily explained by the fact that the spleen is in contact with the left kidney. (*d*) The fact that the absence of the left kidney could not have been diagnosed, so that if the hydronephrotic kidney

Digitized by Google

had been removed without previous drainage, as recommended by Barker, the only working kidney would have been removed. It is, therefore, advisable to drain a hydronephrotic kidney before removing it so as to find out what is the working capability of the other kidney. (*e*) The obstruction which caused the hydronephrosis was incomplete on both sides. (*f*) The renal vessels on the left side had atrophied *pari passu* with the kidney which they supplied, the pyonephrotic sac receiving its blood-supply from the vessels in the fatty capsule.

RIO TINTO HOSPITAL, HUELVA, SPAIN.

CASES OF PERINEAL AND SUPRA-PUBIC DRAINAGE OF THE BLADDER, ILLUSTRATING THE USE OF GLASS-TUBES IN THE SURGERY OF THE URINARY ORGANS.

(Under the care of Dr. W. A. MACKAY.)

THIS series of cases illustrates the advantages of prolonged drainage in some conditions of disease of the urinary tract. The results cannot be ascribed to the fact that glass was the material used to form the drainage-tubes, but it is desired to draw attention to the value of that material in the after treatment of such patients. We are in receipt of a communication from Mr. Haydon Brown with reference to glass tubes for drainage of other than abdominal wounds, and he has forwarded us specimens of tubes which may be more safely used than those at present at our disposal, less liable to break or cause damage to parts. We have tried them, and find them very useful in many cases where at present the ordinary rubber tube causes pain in introduction, readily becomes foul, or where it is necessary to continue the drainage for a long time.

CASE 1.—M. B——, aged thirty-seven, was admitted on May 28th, 1886, much emaciated and confined to bed. He was suffering from urinary abscess in the anterior abdominal wall, seven fistulæ in the perineum, a tight stricture, cystitis of a year's standing, with much pus in the urine. The patient was unable to bear the presence of a catheter when tied in. The abscess was opened and drained. The catheter was again passed four days later. A staff was also passed down to the stricture, and an incision made through the perineum, dividing the stricture; the finger was passed along the catheter into the bladder. A glass-tube was then tied in. The bladder was drained for six weeks. The patient has been seen lately (five years after the operation), and is in perfect health and never passes an instrument.

CASE 2.—R. M——, aged forty-one, was admitted on Dec. 5th, 1889, with a history of ten years' suffering from stricture of the urethra and urinary fistulæ. The urine contained a large quantity of thick, ropy, tenacious mucopus. The bladder, which was contracted and extremely irritable, was drained through the perineum for three months, and gradually but forcibly dilated with boracic acid solution. The patient continues in perfect health, and does not require to pass an instrument.

CASE 3.—J. C——, aged thirty-two, was admitted on Aug. 15th, 1891, suffering from gangrene of the skin of the penis and scrotum caused by extravasation of urine, which followed the bursting of a deep perineal abscess into the urethra; no external opening. On admission the pulse was 130, the scrotum was the size of a fœtal head, with gangrenous patches, and the anterior abdominal wall was dusky red and hard up to the umbilicus. The case was considered hopeless. Carbolic acid and mercury were powerless against the stench arising on incising the gangrenous patches. No urine had been voided for thirty hours. A staff was passed as far as possible. Incision through the perineum on the point of the staff enabled a large solid slough to be turned out, and after clearing a fetid cavity in the deep perineum a glass-tube was passed through the wound into the bladder, and fastened in. Beside the gangrenous patches a large piece of the skin of the anterior abdominal wall sloughed, and the penis was left almost denuded. Twenty-four hours after the operation the pulse was under 100. The patient made a rapid recovery.

CASE 4.—M. D——, aged eleven, was admitted on Feb. 24th, 1888, with a history of stone extending over a period of six years. There was severe prolapse of the anus; the patient was weak, and suffering from malarial fever. Through a supra-pubic incision a phosphatic stone weighing 300 grains was removed. Three large worms were expelled during convalescence. Wound healed; patient discharged April 7th. The boy continues quite well.

CASE 5.—M. C——, aged fifty-nine, was admitted on Nov. 2nd, 1890, with a history of stone for four years. He had severe cystitis, a large prostate, and much pus in the urine. Lithotrity performed a year ago gave little relief. Seven stones (phosphatic) were removed through a supra-pubic incision; the largest was the size of a pigeon's egg. A wide glass-tube was inserted, and replaced at the end of twenty-four hours by one of smaller calibre. The bladder was drained for two weeks. The wound then healed, and the urine was normal. The patient was discharged cured on Nov. 24th. A year later he reported himself in perfect health.

CASE 6.—J. C——, aged seventy-five, was admitted on Dec. 30th, 1891. There was a history of stone in the bladder for eight years. Four years ago Dr. Mackay removed with the lithotrite a large quantity of phosphatic matter, but the relief was only temporary. On admission the patient was suffering from severe cystitis; much pus in the urine, which was ammoniacal; a large prostate; there was no stone. The catheter no longer relieved him. He was worn out by pain and want of sleep. Supra-pubic cystotomy gave immediate relief. The pulse before the operation was constantly over 100. After the operation it never reached 90, and was seldom over 80. A wide glass-tube was used for the first twenty-four hours. This patient was in his chair at the end of the first week. The bladder is to be drained until the urine is normal, and free from pus.

Remarks by Dr. W. A. MACKAY.—Far from imagining that there is anything new in the idea of employing glass in the surgery of the urinary organs, I am rather anxious to learn whether we have any other substance which ought to be preferred. After a trial of all kinds of lithotomy and other drainage-tubes, I have found that the general well-being and comfort of the patient are best attained with glass. Why abdominal surgery should have such a monopoly of this commodity I have never been able to understand; but it is certain that abdominal surgeons through attention to such simple details have reached a position of security from which neither the fear of a germ nor the beautiful colouring of an antiseptic dressing can allure them. I do not attempt to enumerate the advantages of a glass-tube in the drainage of the urinary bladder, but have simply given details of a few cases where glass was used. There has been an entire absence of any grave symptoms after operation in all cases in which I have either opened or drained the bladder. Sufficient time has now elapsed in most of the cases cited to ensure a trustworthy result. The bladder was in some instances drained for a very long time. This, I believe, has a marked influence on the permanency of the result. A patient can wear with little inconvenience a properly fitting tube, and it seems to me unwise to let the wound close before the condition for which it was made is radically relieved. In all the cases a glass-tube was employed, like that used in abdominal surgery, only of smaller calibre. To this is attached a small piece of indiarubber tubing, which conveys the urine to a vessel in the bed, and the patient is kept quite dry and undisturbed. No dressing is used except a T-bandage in a perineal case, and a piece of fine sticking plaster and thread to fix the tube when it is inserted above the pubes. A rectal bag and warm solution of boracic acid were employed at the operation in all the supra-pubic cases. In none of these was there any appearance of extravasation of urine or abscess formation about the wound. In the case of old men the stone is often not the most important factor in the pathological condition of the patient. It may be got rid of by means of a lithotrite, and yet no rest is given to the prostate and bladder. Such cases can only be cured by prolonged drainage, which I venture to suggest might well supersede prostatectomy in many cases.

DEATH OF DR. IMMISCH.—A well-known figure in Heidelberg has just passed away in the person of Dr. Immisch, the Heidelberg "duel" doctor. Dr. Immisch had occupied for over forty years the post of doctor to the students who were wounded in duels. All the students of the Heidelberg University attended the doctor's funeral, each corps bearing its banners and devices.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Enterostomy in Intestinal Obstruction.

AN ordinary meeting of this Society was held on March 8th, the President, Sir Andrew Clark, in the chair.

Mr. JAMES GREIG SMITH (Bristol) communicated a paper on Enterostomy in Intestinal Obstruction. The object of the paper was to advocate operative evacuation and drainage of intestinal contents in cases of obstruction of the bowels where distension was a marked feature. It was shown that mere over-distension of the intestinal walls was a potent factor in the production of obstruction; physical and physiological causes combined to render an over-distended gut incapable of passing onwards its contents. It was argued that the operative treatment of intestinal obstruction was not completed until this continuing cause was removed. According to the nature of the case the measures adopted should be—(1) simple evacuation of contents with immediate return of the gut; or (2) evacuation with drainage for several hours or days, and subsequent closure and return of the gut; or (3) evacuation with drainage that might be permanent. The operative details were described. Anæsthesia should never be carried out while the stomach was distended with fluid; then either the stomach should be artificially emptied, or the operation should be performed with the help of a local anæsthetic. Anæsthesia should be continued only for so long as was necessary to make the parietal incision and place the sutures. 1. The proceeding of simple evacuation was described in detail. The handling and opening of the gut, the means to promote evacuation, and the length of time which it was advisable to spend over the proceeding, the closure, cleansing, and return of the gut, were in turn considered. 2. The proceeding of drainage carried out continuously or intermittently over several hours or days was next described. The means to be adopted for temporary fixation of the gut in the parietal opening, for removing and collecting the intestinal discharges, and for closing the gut and uniting the parietal wound over it, were related. 3. The continuance of drainage for an indefinite period—the formation of fæcal fistula—as the best means of dealing with a certain class of cases was discussed. The position of enterostomy as a means of dealing with cases where the cause of the obstruction was not found, or, being found, could not be removed, was considered only incidentally. The arguments adduced were intended to apply only to cases where over distension existed; and the measures advocated were intended to supplement and complete the ordinary surgical methods for relief of the strangulation, and in no sense to replace these.

Mr. BRYANT said that the paper was evidently the result of considerable observation and experience. Everyone would admit the evil effects of over-distension, which gave rise to paralysis of the intestine. The treatment was not new, for it had often been practised before, but it was a question in which class of case it would be applicable. It was not uncommon to find persistence of symptoms after operation for strangulated hernia, and after death no obstruction would be found; but the knuckle of bowel which had been relieved appeared not to have sufficiently recovered to allow the forcing through it of the intestinal contents, and the bowel above would be paralysed and would not act. Would the author recommend a second operation for the relief of the distension in such a case? He himself thought that a small enterostomy might be advisable. In a second large class of cases of band, volvulus, or other form of internal strangulation the operation was a valuable one. All had probably recognised the difficulty there often was in returning the distended intestine in such cases, and in three he had been obliged to relieve the over-distended bowel by tapping it, though he confessed that he had not done it on the principle laid down by Mr. Greig Smith, but simply as a mechanical measure to aid the return of the gut. Whether the operation for the removal of the cause were done at the time of the relief of the distension or later would depend on the individual circumstances of the case. He agreed with the author as to the details of the operation. He held it to be unnecessary to connect the parietal peritoneum with the skin, and he had never done it in practice; he preferred to allow the bowel to come in contact with the freshly cut tissues and the skin. For years he had performed the operation of lumbar colotomy by pinning the gut in the wound without stitching; after thirty-six hours adhesion would take place, and then the gut could be dealt with in any fashion required.

Mr. KNOWSLEY THORNTON referred to the paper as an interestingly suggestive and valuably practical communication dealing with some of the most unsatisfactory cases of abdominal surgery. He desired particularly to refer to the part played by the parietal abdominal muscles in these cases. They also lost their tone and their power of contracting, and this contributed in no small degree to the distension. Great assistance could be given them by means of firm strapping, aided by padding with towels and cotton wool. He asked if, in the cases in which the intestine required emptying frequently, the multiple points of puncture were each secured by suture. He himself was always in the habit of closing punctures in the intestine by means of a single fine parietal suture.

Mr. PEARCE GOULD said that any suggestion having for its end the increased success of abdominal surgery would be warmly welcomed by all, for it had to be confessed that the results of practice in these particular cases had up to the present time been very disappointing. The chief aim of the author appeared to be a physical one—to relieve an over-distended bowel which was by its over-distension unable to pass on its contents. But he thought that there was generally an additional factor in these cases; that a poison was frequently produced and absorbed which was of a very dangerous character. It was perhaps this poison which rendered the patients so liable to be unfavourably affected by chloroform. Washing out the stomach in cases of fæcal vomiting did great good, and the total effect was more than that which would be produced by the mere removal of the fluid. A few ounces only might be withdrawn and yet a great improvement in the patient's condition follow. The benefit, so to speak, seemed to be a chemical rather than a physical one. A patient might be suffering from acute intestinal obstruction and might not be very bad; he would be submitted to an operation which was not very severe, the procedure being, perhaps, limited to the speedy division of a band, and yet on return to bed he would not recover; the pulse would become more feeble and frequent, and death would take place in an hour or less. At the post-mortem examination the obstruction would be found to be completely relieved, but the bowels remained distended. This had been called abdominal shock, but this term did not at all explain the effect we had to deal with. He related another case in which the patient died suddenly two hours and a half after the administration of chloroform for the relief by operation of a hernia which had been reduced *en bloc*. At the necropsy the small intestine was found to be greatly distended, but no obstruction remained. It seemed that the patient was poisoned by some ptomaine secreted in his intestine. It was certain that the fluid which these patients vomited was not only greater in amount, but was different in its coarse physical characters from the healthy gastric or intestinal fluids.

Mr. THOMAS SMITH held that time was a most important element in all operations done for the relief of strangulation or obstruction, and anything which tended to reduce the time of the operation was worthy of consideration. The suggestion that the amount of chloroform given should be reduced to a minimum was a valuable one. He inquired if the patient was conscious of the grasp which the assistant had of the intestine. He himself had demonstrated many times that the stomach could be cut without giving rise to pain, and he had, in a patient without an anæsthetic, scratched the intestine with a pen, put ink, tincture of aloes, and other fluids on it, and yet the patient had experienced no unpleasant sensation. Another valuable practical point was the division of the operation into two stages, relieving the distension first and dealing with the cause of it later. He asked if any kind of antiseptic was used in these operations. He thought that the parietal peritoneum should be secured, as otherwise it was apt to slip away from the wound and leave a raw surface presenting towards the peritoneum. He referred to the advantages of Paul's tube in these cases: it was easily adjusted, and could be corked so as to regulate the outflow of intestinal contents.

Digitized by Google

Mr. HOWARD MARSH agreed in the importance of this question of distension, which the author had shown could be dealt with by properly contrived methods. He asked if much use had been made of it in its application to the treatment of strangulated hernia. It had been held that the failure of the contents to pass onwards after the relief of the obstruction was due to the paralysis of the gut for some distance above the site of the constriction; and some surgeons, in cases in which it had been necessary to open the gut at the time of the operation, had drawn down and excised a length of the proximal intestine, so as to get above the level of the assumedly paralysed part. He asked the author how he would deal with a case of strangulated hernia in which there was a patent canal and the gut had been opened. Would he make a further opening at some other point proximal to the seat of former obstruction for the purpose of relieving the distension?

Mr. GODLEE inquired what was the size of the needles used, and how would the cæcum be dealt with where the contents were solid. Would he in such a case use a larger instrument? He was obliged to operate the other day on a case of strangulated umbilical hernia in an old man, and he observed that the patient suffered nothing while the gut was being manipulated.

Mr. BARKER asked if the author had ever met with prolapse of other portions of intestine through the wound. Such a mishap had been more than once seen in inguinal colotomy. He asked if any ill effect had been observed from failure to cover the edges of the wound with parietal peritoneum. The advantage of attending to the latter was to keep any oozing out of the peritoneal cavity.

After some congratulatory remarks from the president, Mr. GREIG SMITH replied. He recapitulated shortly the measures he would take if they were dealing with a typical case. If the stomach were distended he would first empty it; then a little anæsthetic should be administered, and an incision should be made where necessary, the exigencies of the particular case determining the site. Three or four sutures were then passed through the abdominal walls, and their ends were gathered in forceps. The anæsthetic was now stopped, and, the patient having come round, the finger was inserted into the abdomen, and a gentle search made for the obstruction. When this was relieved the question arose whether the patient should be allowed to run the risk of recovery without any more being done. If there were much distension he always evacuated and drained, and the delighted expression of the patient bore testimony to the benefit of it. The bowel was drawn out and sponges packed round it, a small incision was made through the muscular coat, and a big needle, such as a Spencer Wells's ascites tube, thrust through the mucous lining; this was attached to a large aspirator not too fully exhausted. After the first gush of fluid had stopped one should then deliberately sit down and wait, if necessary for half an hour, until the successive coils had emptied themselves. A Dupuytren's suture was then inserted, and if the distension were completely relieved the wound was closed; but if not, a loop of thread was passed under it, and it was retained in the mouth of the wound. In a case of intestinal obstruction the operator should be prepared to wait by the side of the patient for at least twenty-four hours. Sutures to fix the intestine in the wound were in most cases unnecessary; a stiff skewer passed under the gut would hold it in place, and a properly applied dressing would prevent prolapse. Solid fæces were not usually found in cases of acute obstruction, the contents being fluid enough to pass through the needle. He held it to be a waste of time to suture the peritoneum to the skin, and, in addition, he considered it to be deleterious to bring the peritoneum into a common suture-hole with the bowel and skin, and thus increase the risk of contamination. The union which took place between gut and raw muscle was much firmer than that which formed between gut and peritoneum. He agreed that it was useful to strap the abdomen to aid the parietal muscles. He could give abundant testimony as to the absolute insensibility of the intestine to pain. He did not use the steam spray, but observed great cleanliness, and used for dressings boracic lint and powder, and also boroglyceride. Formerly he had used celluloid tubing in some cases, but in most it excited a secretion of mucus from the gut, which decomposed readily and would not absorb on any dressing. He had therefore come to the conclusion that he would rather tap three or four times during the twenty-four hours than leave a tube in for that period.

ANNUAL GENERAL MEETING.

The annual general meeting of this Society was held on March 1st, Mr. Timothy Holmes, President, in the chair.

The minutes of the last annual meeting having been read and approved, the report of the President and Council, together with the financial statement, were presented. The latter had been duly audited, and showed that the pecuniary position of the Society, in spite of the increased outlay in connexion with the new premises, was satisfactory. The President then moved that the alterations in the by-laws proposed by the Council be adopted. They were, for the most part, purely technical, being connected with the extension of the radius for resident members and the removal of limitations as to numbers in respect to general practitioners, and were declared duly carried. The President then delivered his annual address, in which he commented upon the unusual length of the list of deceased Fellows, owing to the epidemic and the severity of the preceding winter, and which numbered in all twenty-five. A vote of thanks was proposed by Sir Edward Sieveking and seconded by Dr. Powell. The usual votes of thanks having been accorded to the retiring officers of the Society, the meeting adjourned. The following were elected as officers for the ensuing year:—President: Sir Andrew Clark, Bart., M.D., LL.D., F.R.S. Vice-Presidents: William Selby Church, M.D; George Harley, M.D., F.R.S.; Messrs. Howard F. Marsh and Henry Power. Treasurers: Charles John Hare, M.D., and John Ashton Bostock, C.B. Hon. Secretaries: Frederick Taylor, M.D., and Rickman J. Godlee, M.B., B.S. Hon. Librarians; Samuel Jones Gee, M.D., and John Whitaker Hulke, F.R.S. Members of Council: Alfred Lewis Galabin, M.A., M.D.; Norman Moore, M.D.; John Mitchell Bruce, M.D.; Thomas Tillyer Whipham, M.B; Thomas Barlow, M.D.; Sir Joseph Lister, Bart., D.C.L., LL.D., F.R.S.; J. Neville C. Davies Colley, M.C.; William Henry Brace, M.D.; Messrs. Chas. N. Macnamara and Alfred Pearce Gould, M.S.

MEDICAL SOCIETY OF LONDON.

The Causation and Treatment of Piles.

AN ordinary meeting of this Society was held on March 7th, the president, Dr. Douglas Powell, in the chair.

Dr. LAUDER BRUNTON read a paper on the Causation and Treatment of Piles and Allied Affections. After pointing out that dilatation of the hæmorrhoidal veins might be due to obstruction to the return of blood, either in the liver or at the point where the hæmorrhoidal veins pass through the muscular coats of the rectum, he referred to the various conditions under which the different kinds of obstruction might occur. Over-eating led to congestion by maintaining the liver cells in a state of repletion, thereby interfering with the local circulation. Cold might act either through the liver or by causing reflex contraction of the muscular walls of the rectum, and so preventing the blood finding its way back through the veins. In reference to the influence of cold in causing disturbances of the alimentary canal, he pointed out that the parts of the body most susceptible to chill were—(1) the nape of the neck; (2) the abdomen; (3) the shins; and (4) the feet. Passing to the question of treatment, the author, after alluding to the beneficial effect of mercurial purgatives followed by mild salines in the prevention of hepatic congestion, showed that though large doses of aloes might conduce to the formation of piles by unduly stimulating the muscular coats of the rectum, small doses exerted a contrary effect. Another way of relieving hepatic congestion *a frigore* was to apply hot-water bags to the back of the neck and over the liver. When a patient was subject to piles it was advisable that he should accustom himself to empty the bowels at night, in order to secure rest in the recumbent posture after defecation. Moreover, when there was much irritability it was preferable to use a soft sponge and water, instead of paper more or less harsh. He also advised the introduction of a pledget of animal wool dipped in hamamelis, which acted as a mechanical support and a local astringent. With regard to this he observed that the official extracts or tinctures were not so efficacious as certain

Digitized by Google

proprietary preparations. In obstinate cases he had obtained great relief from the use of the anal pad.

Mr. CRIPPS drew a sharp line of distinction between internal and external hæmorrhoids, both in regard to pathology and treatment. The external, he thought, were far the more common, and were totally unconnected with disorder of the liver. Experimentally he had been quite unable to inject the portal system from the anal veins. He recognised two varieties: the one, in which, as a result of straining or accident, a small vein burst and gave rise to a thrombus in the folds of cellular tissue around the anus; the other, which occurred more frequently, was due to the development of œdematous folds of skin in the same position, which were tender and painful and often due to the presence of a fissure. This, which was really the primary lesion, resulted from constipation or from cracking of the epithelium, as occurred in the lips in cold weather. Internal hæmorrhoids became obvious when inflamed, or prolapsed and strangulated, but attention was still more frequently called to them by hæmorrhage.

Dr. LAZARUS BARLOW was also of opinion that the liver had in most cases nothing to do with the formation of piles, and he cited some forms of hepatic enlargement, such as amyloid disease, cancer, and pylephlebitis, which were not, in his experience, accompanied by hæmorrhoids. He agreed with Sir George Humphry's teaching, that piles resulted mostly from straining.

Dr. CAMPBELL POPE mentioned a case in which an acute attack of hæmorrhoids followed sitting on a wet truss of hay, pain coming on within two hours. Much relief subsequently followed a discharge of blood. He thought that if champagne produced a tendency to the disorder, it was by causing over-distension of the bladder.

Mr. GOODSALL also exonerated the liver from any share in the production of piles. He thought the principal factors were heredity, constipation, and any cause of local congestion. In young women they appeared with remarkable constancy on the right side of the anus near the perineum. Hæmorrhoids were more frequent in people with lax tissues, who were also the subjects of varicose veins and hernia. Sedentary occupations favoured the malady.

Mr. PEARCE GOULD expressed the opinion that there was a great want of proper differentiation in nomenclature in regard to piles, a term which he objected to, and more especially when described as an "attack of the piles." He thought there was very little, if anything, in the view that the liver was an important factor in the production of the malady, which resulted mainly, in his opinion, from straining at stool in connexion with constipation, this being favoured by the brittleness of the epithelium around the anus. He placed great reliance in enemata in the treatment of the disorder.

Mr. BOYCE BARROW said that palliative measures were seldom of any avail, and that the straining often resulted from the presence of internal hæmorrhoids. He dwelt upon the value of an operation and the importance of extreme cleanliness.

Dr. BRUNTON, in reply, said he was glad he had introduced the subject, as it was evidently one which required a good deal more discussion, but he regretted not having given more time to making his views clear. He regarded the liver and variations in its circulation as being only one of many factors in the production of hæmorrhoids. There was no doubt local dilatation of arteries as well as veins, assisted by straining, local irritation, and abrasion. The evidence of congestion in the liver was similar to that of congestion elsewhere—enlargement and tenderness. The liver was liable to vary in size greatly and with remarkable rapidity.

The following is a list of officers elected at the general meeting held on March 7th, 1892:—President: Jonathan Hutchinson, F.R.S. Vice-Presidents: William Henry Allchin, M.B., William Rose, F. de Havilland Hall, M.D., and David Henry Goodsall. Treasurer: Arthur Edward Durham. Librarian: William Henry Allchin, M.B. Honorary Secretaries: Arthur Marmaduke Sheild and William Pasteur, M.D. Honorary Secretary for Foreign Correspondence: Jean Samuel Keser, M.D. Council: Charles Alfred Ballance, Albert Boyce Barrow, Thomas Bridgwater, M.B. (Harrow), Charles James Cullingworth, M.D., Joseph Ewart, M.D. (Brighton), George P. Field, Thomas Colcott Fox, M.B., William F. Haslam (Birmingham), George Allan Heron, M.D., Donald W. C. Hood, M.D., Charles Bell Keetley, Augustus Cooper Key, Percy Kidd, M.D., Stephen Mackenzie, M.D., Joseph Arderne Ormerod, M.D., Stephen Paget, Richard Douglas Powell, M.D., William Travers, M.D., George Robertson Turner, and Samuel West, M.D.

OBSTETRICAL SOCIETY OF LONDON.

Cæsarean Section.

AT the meeting on March 2nd, Dr. J. Watt Black, President, in the chair, the following specimens were shown:—

The PRESIDENT: Professor Braun's (of Vienna) Axis-traxis Forceps.

Dr. HANDFIELD JONES: (*a*) Fœtal Monstrosity; (*b*) Hydrosalpinx and Ovarian Cyst.

Dr. HORROCKS: Uterus Extirpated for Cervical Cancer.

Dr. AMAND ROUTH: Uterus Extirpated for Cancer of the Body.

Dr. RUTHERFOORD: Fibroma of Ovary.

Three papers on Cæsarean Section were then read.

Dr. LEITH NAPIER communicated notes of a case on which he operated on June 14th, 1891. The patient was a secundipara, having been delivered of her first child by craniotomy and embryulcia on March 15th, 1890. She was a squat-built woman, 4 ft. 10 in. high, with well-marked rickety curvature of the left tibia. The pelvis was of the contracted, flat variety, with a conjugata vera of 2⅝ in. The Sänger-Müller modification of the Cæsarean section with deep and half-deep sero-muscular sutures was performed 280 days from the date of the last period. Labour had not begun nor had any means been adopted to excite pains. The placenta was situated on the anterior wall. The operation lasted forty-six minutes. Some delay arose on account of the flabby state of the uterus. The sutures were of sterilised silk. The Fallopian tubes were tied in two places and divided between the ligatures; the ovaries were not removed. There was some post-partum hæmorrhage. A severe attack of pleuro-pneumonia followed, but there was no peritonitis or appearance of general sepsis. Recovery was good. The patient went home well thirty-four days after operation. The child (a male) is alive and well.

Dr. JOHN SHAW read notes of a case on which he performed Cæsarean section for contracted pelvis. The patient, an unmarried primipara, was 4 ft. 5 in. high. The pelvis was very rickety, the true conjugate being 2½ in. Sänger's modification of the operation was performed before the actual onset of labour. There was not much loss of blood. Chromic catgut sutures were used—stout, deep, interrupted ones, and a few continuous peritoneal ones. The ovaries were not removed, but the Fallopian tubes were tied with silkworm gut. The child was delivered alive and left the hospital well. The mother suffered from septicæmia due to the retention of some shreds of decidua, but recovered after the uterus had been repeatedly washed out. She left the hospital well.

Dr. CULLINGWORTH narrated the case of a rachitic dwarf, aged twenty-one, 4 feet 5 inches high, on whom he operated on Oct. 8th, 1891. Her general health was good, her pelvis was obliquely as well as generally contracted and flattened, the conjugata vera being from two and one-third inches to two inches and a half. The operation was performed a few days before labour was expected. The uterus was rotated on its long axis so that the right appendages were almost directly in the line of incision. The uterus was opened *in situ*, but was brought out of the abdomen after being emptied, to facilitate the introduction of the sutures. The child, a well-formed male, weighed 7 lb. 7 oz., and cried on delivery. The elastic ligature was not used. There was very little hæmorrhage, the uterus contracting well. Ten deep silk sutures were inserted, and between each two a half-deep suture was passed. No douching or swabbing of the uterine cavity was used. Sterilisation was effected by ligature of each Fallopian tube. The lochial discharge scarcely amounted to more than a stain. The patient left the hospital well twenty-four days after the operation.

Dr. MURDOCH CAMERON (Glasgow) said he was strongly in favour of the Cæsarean section over the Porro-Cæsarean operation. He had performed Cæsarean section fifteen times with only two deaths, and these were in no way due to the operation. He described his method of procedure. First, if labour has not set in, it should be induced; then a five- or six-inch incision in the abdominal wall ought to be made. The uterus is not brought out

Digitized by Google

until after the fœtus has been extracted. Any rotation is carefully rectified, and a small incision made in the median line until the membranes (which must not be ruptured) are reached. Next the incision is enlarged upwards and downwards on a bistoury, the hand introduced, and the child extracted. The uterus is now brought out and thoroughly emptied of placenta and membranes. The edges of the uterine incision are everted by an assistant and deep carbolised silk sutures inserted, with, if necessary, a few superficial catgut ones. He strongly deprecated any interference with the uterus after the operation by using intra-uterine douches or by the introduction of a drainage-tube. The debate was then adjourned to the next meeting.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Obstetrical Section was held on Feb. 12th, Dr. Horne, President, in the chair.

Exhibits.—Dr. W. SMYLY: (*a*) Six cases of Pyosalpinx; (*b*) Three Uteri Extirpated for Cancer.

Dr. MACAN: (*a*) Fibrocystic Tumour of Uterus; (*b*) Double Dermoid Cysts of Ovary; (*c*) Dermoid Cyst of Ovary with Cancerous Degeneration of Cyst Wall.

Notes of a Case of Ruptured Uterus, with Recovery.—Dr. BARRY said: "The patient, aged thirty-five, a primipara, was thirty-eight hours in labour when I saw her; liquor amnii had drained away early in labour. On making a digital examination, os uteri about the size of a florin, thick and rigid. On passing my finger through the os uteri I detected a tear passing in an oblique direction for about four inches. No prolapse of intestine. Promontory of the sacrum easily felt, with vertex presenting at the brim of the pelvis. Conjugate diameter measured three inches. Having passed a catheter and drawn off about a pint of bloody urine, I got an assistant to steady the uterus. Keeping pressure in the axis of the brim of the pelvis, I incised that portion between the os uteri and the tear. Applying forceps, I failed to deliver. Perforated head, when an easy delivery was effected, but considerable difficulty was experienced in extracting the shoulders. The placenta, which was morbidly adherent, was attached to the fundus and slightly posteriorly. The patient made a good recovery. I saw her three months after delivery, when, on examination, the uterus was found normal in size and position, menstruation being normal and painless. Os externum quite small, admitting with difficulty the point of a sound, very little evidence of rupture remaining."—Dr. ATTHILL said the case as described by Dr. Barry was a remarkable one, and, as far as he (Dr. Atthill) was aware, no similar one had been recorded. Here was a woman thirty-eight hours in labour, and in whom the waters had long before drained away, with so small a conjugate diameter that the head never came in contact with the os, yet a rent occurred in a position so situated that the finger passed into the os could detect it; it evidently was a rupture of the cervix. How it could have occurred under the conditions detailed Dr. Atthill was unable to explain.

Fæcal Fistula following the Removal of Abdominal Tumours.—Mr. M'ARDLE read a paper on this subject. After detailing cases of this trouble he explained that the condition seemed to be due to extension of suppuration from the tumour into the intestine, ulceration from the intestine extending into the tumour, local necrosis of the bowel wall due to pressure of the tumour, tearing of the coats of the bowel during the operation, disturbance of the nutrition of the bowel owing to injury of the vessels of the intestine, and constant pressure of the glass drainage-tube in contact with the bowel. In reference to the treatment, Mr. M'Ardle said: "The situation of the opening in the bowel will more than any other circumstance determine the extent of surgical interference. While referring to this matter, there is one method of determining the site of perforation which does not seem to be as generally recognised as it deserves. I refer to inflation with hydrogen gas. As a diagnostic aid, gaseous distension is infinitely superior to the injection of fluids, since it does not interfere with the steps of any operation which may be deemed necessary after its use, while fluids are a source of constant annoyance during suture of the bowel. Often the character of the discharge suffices to show the position of the opening; at other times the relation the intestines bear to the tumour indicates the locality of the fistula. When the opening is in the rectum, closure is almost certain, owing to (*a*) fixity of this portion of the gut, (*b*) great vascular supply, and (*c*) the chance of extra-peritoneal healing, hence early operative interference is contraindicated."—Dr. ATTHILL had met with three cases of fæcal fistula in his practice. In one of them the case had been diagnosed as one of suppurating ovarian tumour. The operation was performed under very unfavourable circumstances, the temperature before it being 103°. The tumour proved to be a suppurating one, and in addition there also was a deep-seated pelvic abscess, which during the removal of the tumour ruptured, discharging very fetid pus. In this case fæces were discharged through the wound on the fifteenth day after the operation. Dr. Atthill thought in this case it was due to the softening of the intestines at the seat of the pelvic abscess. This patient recovered perfectly, the fistula closing in about six months. In the second case the fistula formed on the tenth day after the operation, the tumour being a small ovarian one, very firmly bound down by adhesions in the left inguinal fossa. An operation to cure the fistula was performed nearly a year after, which ended fatally. The third case was one which occurred seven days after vaginal hysterectomy for malignant disease. The fæces were discharged per vaginam for a few days; the fistula then closed.

Reviews and Notices of Books.

A Treatise on the Ligation of the Great Arteries in Continuity, with Observations on the Nature, Progress, and Treatment of Aneurysm. By CHARLES A. BALLANCE, M.S. Lond., F.R.C.S., Assistant Surgeon to St. Thomas's Hospital; and WALTER EDMUNDS, M.A., M.C. Cantab., &c., F.R.C.S., Resident Medical Officer at St. Thomas's Home. Illustrated by 10 Plates and 232 Figures. London: Macmillan and Co. 1891.

FOR many reasons the pathological and clinical questions which arise in connexion with the ligature of large arteries are, and will probably always continue to be, of great interest and importance. Although the introduction of antiseptic surgery has profoundly influenced the course of wounds and the results of operations, it has not as yet been followed by those perfect results in cases of ligature of great arteries that have been obtained with other tissues. The authors of this work are able to show that even the most recent results of operations upon great arteries are by no means satisfactory, and that the danger of secondary hæmorrhage is still a very real and pressing one. The chief object of Messrs. Ballance and Edmunds is to show how this failure comes about, and how it may be avoided. To obtain the solution of these problems they have carried out an elaborate series of experiments which have occupied them for six years, and which they in this treatise fully detail. The main results they have obtained are not new, although they are now supported by exact and minute observations, which were not possible in earlier days. Since the publication in 1810 of Jones's classical work on Hæmorrhage, surgeons have generally sought so to tie their ligatures as to rupture the inner and middle tunics of the arteries, and have regarded such a rupture as an additional security. On looking back it is evident that such a conclusion was too hastily arrived at. Jones's experiments were not completed, and his dicta were opposed to the clinical experience of some of the leading surgeons of the day. So it has always been. Men arise from time to time whose writings have an undue influence upon their fellows, whose opinions are accepted too readily and too generally, and Jones seems to have been of this number. For nearly a century his work and his teaching have been unquestioned, and have formed the basis for the surgical treatment of arteries in Europe and America. The experiments of Messrs. Ballance and Edmunds show—we think conclusively—that the division of any portion of an

Digitized by Google

arterial wall by a ligature is unnecessary for the accomplishment of its obliteration, and that it in no way so facilitates its obliteration as to compensate for the grave danger it introduces by the serious weakening of the vessel. It is shown that simple occlusion of a vessel without any laceration of its walls will be followed by its permanent obliteration, and that the proliferation of the endothelial lining of the intima plays a very important part in the organisation of the clot. Stress is also laid upon the comparative tenuity of the walls of the main arteries during life, and especially of the outer coat, and so a very strong case is made for the contention that ligatures should be tied so as to occlude a vessel, but not to rupture any part of it. The many factors in the problem are separately dealt with—the conduct of the corpuscles, of the coats of the artery, of the ligature, and of the aneurysm. The great majority of the statements made are based upon the authors' own experiments, and no labour has been spared to make the investigation thorough and complete. But the book is far more than a record of personal work and opinions; the work of others is cordially recognised, and the literature of the subject is largely referred to and drawn upon. The result is a volume highly creditable to its authors. That all their conclusions will stand the test of experience we cannot say. Many will no doubt differ from them on the matters of the best ligature material and of the most reliable knot. What the authors call the "stay-knot" has certain apparent disadvantages which may prevent its general adoption. But the candid reader will be slow to question the results arrived at by such evidently painstaking and impartial observers as Messrs. Ballance and Edmunds, and will be careful not to let prejudice bias his judgment.

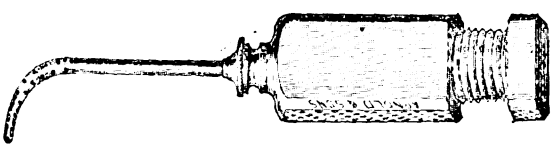
The work has been issued as an *édition de luxe*. The paper, the type, and the illustrations are all that the most fastidious of book fanciers could desire. In fact, we are inclined to think that too much attention has been given to the mere form in which the book is issued. Its bulk is unduly large, and will no doubt frighten some who would otherwise read it. The text, too, could bear a good deal of compression without any sacrifice of cogency in argument or richness of illustration. But such criticisms are perhaps a little censorious in these days of many and cheap books, sometimes badly written, badly printed, and insufficiently illustrated.

The Human Figure: its Beauties and Defects. By ERNST BRÜCKE, Emeritus Professor of Physiology in the University of Vienna; with a Preface by WILLIAM ANDERSON, F.R.C.S., Professor of Anatomy to the Royal Academy of Arts and Lecturer on Anatomy at St. Thomas's Hospital. 1891. London: H. Grevel and Co.

No book could be more welcome to the English artist and anatomist than this translation of Professor Brücke's "Schonheit und Fehler der menschlichen Gestalt," and we congratulate Mr. Anderson on marking his election to the professorship of anatomy at the Royal Academy by the publication of such an excellent translation of this most interesting and valuable work. By it we are reminded that before becoming a great physiologist Professor Brücke was a teacher of anatomy in the Academy of Fine Arts in Berlin, where his love for art, doubtless inherited from his father, and his knowledge of anatomy made his lectures and writings eagerly attended and perused by students of art and those who wished to gain a proper insight into the ideal construction of the human frame. As Professor Anderson well remarks in his preface, "an anatomist may be no more competent to give a verdict upon a question of the beautiful than a person who has never heard the name of a single muscle in his body; ..... on the other hand, such a familiarity with the human figure as may be gleaned by casual and unreflecting observation is of no greater value." Professor Brücke has wisely combined anatomical considerations with criticism of the external form, but has only introduced such anatomical details as are necessary to convey accurate general ideas, so that he might not weary the artist with mere technical anatomical knowledge. The work is most clear and interesting throughout, whether judged from the artistic or the anatomical standpoint. The body is divided into seven sections, beginning with the head and neck and finishing with the legs and feet. An extract with regard to the length of the toes will give sufficient evidence of the breadth of view and knowledge of detail which characterises the whole work. "Some authorities insist that the great toe ought to project furthest, others that it should not project quite so far as the second toe; while others, again, maintain that the two should be of equal length. It is well known that in antique statues the second toe is usually the longer of the two, while the first is longer in living men. Some persons are of opinion that the latter condition is a consequence of wearing boots and shoes, while others hold that the longer second toe in the antique is an artistic figment. Both are in the wrong." To prove this, he then gives the exact measurements of the foot of an old man in whom the second toe was obviously longer than the first, and yet the man had worn ordinary footgear from his earliest youth. To show that in addition to external influences personal and racial characteristics must be considered, he next instances an Egyptian fellah girl, in whom the great toe was conspicuously longer than the second, although she had certainly never worn shoes of the European pattern, and probably not any at all. That it is not an artistic fiction is clear from the statement of an Italian sculptor, that though in Italy it is the exception for the second toe to exceed the first in length, yet this is not infrequently to be met with. Hence Professor Brücke concludes that an artist is justified in representing the feet on the type which he regards as the most beautiful among the forms actually observed by him, and not necessarily as in his model. The work is most artistically printed, and the illustrations by Hermann Paar are quite worthy of the book. It is a matter of some slight satisfaction to English anatomists and artists that the drawings, although reproduced from Hollstein's "Anatomie des Menschen," are really copies from the well-known woodcuts of the brothers Bagge, in Wilson's "Anatomist's Vade Mecum."

Journeys in Persia and Kurdistan. By Mrs. BISHOP. London: John Murray.

MRS. BISHOP is well known, under her maiden name of Isabella L. Bird, as a writer of books of travel which have attained a wide reputation. This latest issue from her pen is in the form of a series of letters written from Persia and Kurdistan, which depict in a very graphic manner the incidents encountered in the course of a prolonged and by no means uneventful progress through these little-known regions. In her preface the writer apologises for a supposed want of accuracy, the result of defective revision, she having suffered the loss of some carefully made notes which had been prepared for that purpose. It is not, however, in these respects that the lack of editing will be felt by her readers, for the letters, having been originally written with a view to publication, are eminently readable, notwithstanding the disadvantages under which they were produced. But it is not easy to repress all complaint of the entire absence of index, table of contents, or argument at the heading of the chapters. The only indication which is afforded to Mrs. Bishop's readers of the subject of the text is a single phrase, which is superscribed to the page. Small as it may seem, this omission will seriously impair the book



Digitized by Google

for the purposes of reference, since it is nearly impossible to recover a passage, though remembered, without such guidance, and quite impossible to find one's way about the book without reading it through. The glimpses of Eastern life and manners which the letters afford are for the most part exceedingly interesting, and although the monotonous badness of the roads gives rise to a certain sameness in much of the narrative, even this circumstance produces a stronger impression than could otherwise be conveyed of the serious material obstacles to progress in these backward countries. An interesting story is told of Mrs. Bishop's visit to a harem on the Persian frontier. The principal wife of the local magnate was suffering from a tumour, upon which the medical man in attendance desired to operate, being of opinion that only by surgical treatment would his patient's life be saved; but, although urged to act upon his views and to accept Mrs. Bishop's services in the capacity of a nurse, he replied that if the patient were to die he would in that case be accused of murder.

New Invention.

OINTMENT INTRODUCER.

ALL who have much to do with the treatment of scarlet fever with, amongst its many complications, that of rhinorrhœa, must not infrequently be annoyed at the failure of success with the conventional syringing by means of the ordinary apparatus, not to mention the difficulties, details, and now and then struggles that are associated with the operation on very young children. For some time past I have employed an ointment introducer, identical with Mr. Allingham's, except that the stem is made of electro-plate,

of less size, perforated with a set of thirty-three holes, arranged in lines of eight, with one at the extremity. Being curved exactly similar to a Bellocq's cannula, its introduction is, as a rule, equally easy, except when there is excessive blocking of the nostrils by hypertrophy of the mucous membrane. By means of this contrivance, admirably worked out by Messrs. Arnold and Sons, London, ointments of all kinds are readily and freely placed upon the whole surface of the inflamed parts, and the quantity so introduced is regulated to a nicety by the screw at the end of the box, composed of either boxwood or vulcanite. Its cost and simplicity are such as, I venture to think, to recommend it; at least as a supplement to the means at our disposal.

WM. GAYTON.

THE ETHICS OF LIFE INSURANCE AND MEDICAL CERTIFICATES.

To the Editors of THE LANCET.

SIRS,—As another "M.D.," let me corroborate every statement as set forth by a "Doctor of Medicine" in *The Times*. My district is a manufacturing one, where the major portion of the inhabitants—men, women, and children—are insured in one or several insurance offices. The more precarious the life, the larger the amount, the greater the number of offices insured in. The "necrologist" lives and thrives here. His or her method of procedure is as follows: The patient is generally brought to a practitioner whose prognosis can be relied on. His opinion is sought, and, if unfavourable to a long duration of life, the person is rushed forthwith into several insurance companies. The insured one then invariably becomes an out-door patient to an infirmary, and, finally, when the disease has reached a critical stage, a practitioner (not the prognostic one, but one of the "good' sort) is called in, and death ensues. No mention is made of the first practitioner nor of the out-door attendance. No; the patient was attended in her last illness by Dr. ——, and the illness lasted one month!

I am in attendance at present on a family all of whom have a phthisical diathesis. One member, who died about two years ago, was examined by me, and I pronounced her phthisical. Instantly she was rushed into several insurance companies and insured to the amount of £70, the relatives all partaking of the spoil after her death. The family are so poor that my bill is paid at the rate of about sixpence per week. Two other members have lately shown signs of the same disease, and I have no doubt are insured for an equal if not a greater amount. Another patient died a fortnight ago—a case of chronic phthisis, in my opinion of about two years' duration. He was a poor man; insurance money £40. Another last week; insurance money £60. To do what is known as "good business," the agents of the companies will insure all and everyone; all is fish that comes to their net.

Now for the ethics. A proposal in cases like these is made by the person who comes for the certificate. Could not you put it down bronchitis, doctor? If cancer, could not you say a tumour? This is put very innocently, as I suppose they want the tumour described accordingly. The practitioner stands firm, and puts down phthisis or cancer. Instantly he is swooped down on by the agents of the respective companies, and asked, impudently very often, to furnish them with full particulars regarding these cases. I invariably show such persons the door. They are strangers. They always remonstrate, and have informed me that it is customary for the practitioners in the district to furnish them with full particulars, and furthermore that they are willing to pay for the information! If this is so, it speaks very badly for the honourable confidence which is supposed to exist between the medical attendant and his patient. I regret to say it is done. One agent of a large company to whom I refused information informed me that a phthisis certificate was the first they have had for the last two years. And this in a district where phthisis is so prevalent, and the competition of this company so keen, most of their people being accepted without an examination. Amongst the industrial classes the statistics of the Registrar-General, as regards phthisis, cancer, &c., in my opinion must be taken with a goodly pinch of salt. It is marvellous how death rejuvenates the insured. People who are, and who appear to be, seventy or eighty bloom forth on a death certificate as fifty or sixty. "Mens conscia recti" is, as "Doctor of Medicine" insinuates, the sole reward for signing his death certificates properly. For him there is no refereeship. He is boycotted by the agents, for they are all "honourable men." He must either dishonourably divulge his professional secrets to every stranger who says he represents an insurance office, or accept the other alternative, falsify his death certificate and keep on good terms with the life insurance agents and with his patient's friends. I hesitate to touch on the insurance of children. God alone knows all that it is responsible for. One instance may suffice. I was present some years ago at an annual meeting of an insurance society which was and is doing an extensive business in this district. The agents and collectors were delivering their customary after-dinner speeches. One man got up and related amidst great applause how he out-manœuvred another agent of a competing insurance company. There were four children in the family. He had two; his rival two. But, with a knowing wink, he informed the company present that he had got the fifth. The woman was far gone in pregnancy, and he had entered the unborn child on his books and paid for it in advance! Comment on this is needless.

I am, Sirs, yours faithfully,

Feb. 29th, 1892. ANTI-NECROLOGIST.

SUICIDE OF A MEDICAL PRACTITIONER.—Last week Dr. John Grime of Great Bolton-street, Blackburn, J.P., a surgeon in large practice, and a borough magistrate, was found by Dr. Irving, his partner, lying on the floor of his dining room, with a bottle of prussic acid by his side. Three months ago he suffered from influenza, and subsequently had been very depressed in spirits. He was forty-eight years of age.

THE LANCET.

LONDON: SATURDAY, MARCH 12, 1892.

THE approaching visit of Her Majesty the QUEEN to Hyères naturally invites attention to the climate and general characteristics of that health resort. Hence an article in the *Climatologist*, from the pen of Dr. C. E. CORMACK on Hyères and the French Riviera comes opportunely at the present moment. He claims for Hyères that it is the most southern of the winter resorts of the Riviera, and that it is also the warmest, and at the same time possesses the most equable temperature and the advantage of having the closest contiguity to England." The principal town is distant about three miles from the Mediterranean, while one of the suburbs—Costobelle—is almost on the sea, invalids having thus the choice of the more bracing marine, or more sedative inland, situation. Hyères has as protectors against the northerly and Alpine winds Mount Fenouillet, 981 feet high; Mount Condon, 2305 feet high; and the Maure range, 2556 feet high. On this very important subject of wind Dr. CORMACK writes as follows:—"During the autumn months the east, west, and north winds are those most frequently met with, and they all blow in about the same proportion. During the winter the winds are much more violent, and sometimes there are very violent storms, which have a marked influence upon the temperature, and may cause a sudden fall of from 6 to 10 F. The reigning winter winds are north, north-east, and north-west. The latter wind is popularly known in the country by the name of the 'mistral.' It is a most searching wind, and very trying to invalids and those of a nervous temperament. ..... The mistral is not peculiar to Hyères, however; it is to be met with all along the Riviera, and in very much the same proportion."

We are curious to know upon what authority Dr. CORMACK bases his statement that Hyères does not suffer from the mistral more than the other Rivieran resorts, or whether he can furnish any trustworthy meteorological observations in support of that assertion. We thought it was generally admitted that, while this troublesome and dangerous wind was the curse of Marseilles and the more western resorts of the Riviera (especially Hyères), it was very much less prevalent and annoying at Mentone and San Remo. On this subject Dr. SPARKS writes as follows in his well-known handbook on "The Riviera":—"The curse of Hyères is the north-west wind or mistral, which not unfrequently rages with great violence, sweeping in tremendous gusts down the valley of Hyères on to the town or plain. ..... The mistral blows at Hyères on upwards of sixty-four days in winter, spring, and autumn, according to the observations of Dr. BATTAILLE for the years 1816-25. ..... I myself noted it fifteen times between April 12th and May 21st, 1877, and on six of these days it is marked in my notes as 'rough,' and on two others as 'furious.'" The same high authority gives the average number of days on which the mistral prevails at Mentone from November to April as from twenty-three to twenty-four, and its force (especially on the east bay) is described as usually so moderate that it has even been questioned (erroneously, however) whether the true mistral prevails at Mentone at all.

As evidence of the mildness of Hyères Dr. CORMACK adduces its well-known wealth of trees, flowers, and vegetables. Orange trees abound; the olive is largely cultivated; palm trees are to be seen on every hand; early vegetables are raised in large quantities for the northern market; and an immense trade is done in the exportation of roses, violets, anemones, mimosæ, hyacinths, &c. The temperature at Hyères during the winter months ranges from 50° to 59°F. between the hours of 8 A.M. and 4 P.M., taken in the shade, and from 75° to 85°F. taken in the sun. "The early morning and the evening temperatures are often very low, and there is always a rapid fall in the thermometer after sunset, frequently as much as from 7° to 9°F." This last feature is common to all warm and dry or moderately dry climates, and is due to the energy of radiation. Snow is very rare, but not unknown, at Hyères. Frost during the night and early morning is not uncommon. Cloudy days are rare, blue sky being the rule.

As regards rainfall, Hyères comes out well in the comparative tables. Statistics based on the returns for twenty-six years show that out of the 243 days included in the months from October to May there were only thirty-six wet days, while Nice is credited with fifty-one, Cannes with fifty-four, and Mentone with sixty-four. The average number of wet days per month at Hyères was four or five, October and December being the wettest months, and March the driest. Sufficient statistics do not exist for determining the average rainfall at the various resorts, but there are good grounds for believing that the fall at Hyères is less than at Nice, Cannes, or Mentone. We may remark, however, that far too much stress is often laid upon this point in comparing the relative advantages of various health resorts. A few inches of rain more or less is a matter of no consequence at all to the invalid, except as a gauge of the amount of sunshine and number of fine days that may be expected. A rainfall of thirty inches may coexist with 150 or 180 wet days in the year, while in another locality where the rainfall is less frequent but more violent we may find only 60 or 80 wet days in the year, but a total precipitation of perhaps fifty inches or more.

Hyères is, according to Dr. CORMACK, "admirably suited to cases of phthisis. Should the disease be in its first period when the patient arrives, a complete cure may take place. The same result may be obtained with cases which have arrived at their second period, although the chances are less, but in any case a considerable improvement may be expected. When the disease has passed into its third period, or is too far advanced for any reasonable hopes of recovery to be entertained, life is prolonged for a time." These rules are at once much too vague and too roseate. Many cases of phthisis, even in the first stage, are wholly unsuitable for the Riviera, and the benefit to be expected in the second and third stages is always problematical. To discuss this question adequately would take us much beyond our present limits, but we may say in a general way that the Rivieran climate is somewhat stimulant and excitant, and should be avoided for cases of

Digitized by Google

phthisis of the erethic type, or where nervous symptoms are prominent. The presence of anæmia, rheumatism, or renal complications is, on the other hand, an indication *quantum valeat* for the Riviera.

As regards other diseases, Dr. CORMACK informs us that "all chest complaints and bronchial affections improve under this genial climate. Liver complaints, affections of the kidneys, Bright's disease, diabetes, &c., are all favourably influenced by the warm and equable temperature. Gouty and rheumatic cases get on very well here [i.e., at Hyères] and generally are much relieved after a winter or two's residence. ..... Cases of anæmia and asthma also do remarkably well." These statements are also somewhat too sweeping, though in the main correct. The Riviera is very useful in bronchial affections, in Bright's disease, in gout and in rheumatism. We are less sure of its beneficial influence with regard to affections of the liver; and asthma is too erratic a disease, as regards its relation to climate, to admit of any very definite rules regarding it being laid down.

ANY contribution towards the better comprehension of diphtheria must be welcome, and it is a singular fact that for some years after its discovery by KLEBS, and subsequent rediscovery by LÖFFLER, there should have been comparatively little attention paid to the bacillus, which is now on all sides recognised as being the prime agent in the disease. It was not, indeed, until ROUX and YERSIN succeeded in showing that the products of the cultures of this organism give rise to some of the characteristic effects of the virus, including paralysis, that the etiological relationship of the bacillus to diphtheria could be said to have been established. This point in the history of the subject was brought out by Professor BAGINSKY in a paper recently read before the Berlin Medical Society, that occasioned a discussion which occupied two sittings.[1] It may be remarked in passing that Professor BAGINSKY, in giving so much credit to the French observers, did not escape the criticism of one of the speakers, who pointed to the long array of German men of science who had worked at the subject; but Professor BAGINSKY successfully maintained his ground. The main purport of his communication was to develop what may be termed the bacteriological diagnosis of diphtheria, and to advocate its routine employment as an adjuvant to clinical observation. During the past year he has been engaged at the Hospital for Sick Children, which bears the names of the Emperor and Empress FREDERICK, in obtaining tube cultures from the false membranes of all cases admitted with the diagnosis of diphtheria. Blood-serum was used for the cultivations, which were carried on at a temperature of 37°C. In most cases the microbes found in association with LÖFFLER'S bacillus disappeared, and there was left a pure culture of the latter, which in a few hours assumed its typical and easily recognisable characters. This test was supplemented by microscopical examination of dry preparations, and, in doubtful cases, by the results of inoculation on animals. A pure culture of the bacillus was obtained in 118 out of 154 cases thus examined; of these 118, 45, or more than 38 per cent., proved fatal. Thirty-nine of these cases were associated with paralysis, 17 with severe septic phenomena, and 44 cases required tracheotomy; whilst only 28 (or 25 per cent.) ran a mild and favourable course. On the other hand, there were 36 cases of the whole group from which the deposit yielded no bacilli, but only cocci; and it is particularly instructive to note that only 4 of these were fatal, one being a case admitted with severe paralysis, another complicated with measles and dying from pneumonia, and two developing bilateral empyema. All the rest ran a favourable course, and recovered in a few days without complications. The inference drawn by Professor BAGINSKY from these facts is that there are two types of disease, indistinguishable in their superficial characters, marked by a deposit of false membrane on the fauces and tonsils, and associated with fever, prostration, and swelling of lymphatic glands. The one is true diphtheria, and is caused by LÖFFLER'S bacillus; it is of far greater severity than the other, which appears to be excited by staphylococci and streptococci, and runs mostly a favourable course. Nor is the latter so remarkably contagious as the former; whilst he has known the bacillary disease to supervene upon and prove fatal in a child who had gone through the milder affection. So convinced is he of the value of this distinction that he has devised apparatus for conducting this bacteriological inquiry as a part of clinical investigation; but, as was pointed out by Professor HENOCH, the time required to obtain the characteristic cultures would render of little use the information gained therefrom. Moreover, as other speakers said, the delicacy of bacteriological experimentation was such that it could hardly be expected to become the appanage of every clinician. Professor BAGINSKY'S research further led him to establish that the mild and non contagious malady known as "rhinitis fibrinosa" was dependent on LÖFFLER'S bacillus. At any rate this microbe was found in the membrane from two cases of this affection, suggesting, he said, a relationship to diphtheria akin to that of varioloid to variola. On the other hand, he proved by the same method of investigation that the so-called scarlatinal "diphtheria" has nothing to do with true diphtheria. For, in all the cases of this class that he had examined, he had never once found the bacillus of LÖFFLER, but only cocci in the false membrane. Moreover, in cases of true bacillary diphtheria, upon which scarlet fever or a scarlatinal rash supervened, the growth of bacilli was replaced by that of cocci, thus appearing as if a new contagium had driven the old one out of the field.

As might have been expected, this novel method of diagnosis and the ideas that flowed from it gave rise to considerable discussion. Dr. RITTER, who had some years ago pursued a similar inquiry, had also found the bacillus absent in a certain number of cases of supposed diphtheria. He pointed out that one great distinction between septic disease and diphtheria consists in the fact that the diphtheria bacillus is only to be found locally in the false membranes, whereas in septicæmia streptococci are met with in the blood. He repeated the well-recognised clinical fact that diphtheria may by its local lesions afford entrance to septic organisms; and as regards scarlatinal angina, he said that he had found the diphtheria bacillus in one out of nine cases examined. Dr. ZARNIKO protested warmly against the labours of

[1] Berliner Klinische Wochensch., Nos. 9 and 10, and Deutsche Med. Wochenschr., No. 10, 1892.

Digitized by Google

German investigators upon the diphtheria contagium being ignored, and said that no new facts had been adduced by Professor BAGINSKY. He thought, however, that the latter's observations on scarlat fever were of importance, but could not reconcile the discovery of LÖFFLER'S bacillus in the purely local affection—rhinitis fibrinosa—with the known history of the diphtherial virus. Dr. TROJE said that, after all, the application of Professor BAGINSKY'S test would not *give certainty* to a diagnosis of *true* diphtheria—that could only follow on the results of inoculation; and for his own part he would not regard the occurrence of a streptococcal invasion of the injured parts with such favour as Professor BAGINSKY would, since it points to a septicæmic condition. He alluded also to observations by BARBIER and DAHMER which went to prove that a "mixed infection" of the diphtheria bacillus and of streptococci was of the greatest gravity. Dr. B. FRAENKEL admitted the occurrence of a non-bacillary membranous pharyngitis; he doubted, however, the practical utility of placing the fine methods of bacteriological analysis in the hands of private practitioners. Professor HENOCH spoke in much the same strain, doubting if the methods described could add much to clinical facts which pointed to the relative severity of attacks of alleged diphtheria. He hoped, however, that the vexed question of the nature of primary membranous croup would be determined by these methods of research; and he was pleased to find a confirmation of the view he had long held as to the non-diphtheritic character of membranous exudation in scarlet fever confirmed. Dr. SCHEINMANN desired more information as to the presence of the diphtheria bacillus in rhinitis, which was a purely local affection. If correct, the observation would tend to mitigate the unfavourable prognosis which the presence of the bacillus might convey. Dr. P. GUTTMANN was sceptical as to the non-diphtherial character of cases in which the bacillus was not found, urging that it might have been present at an earlier stage, and had then been replaced by other microbes. He also asked as to the relationship of primary croup to diphtheria. The debate was closed by the President, Professor VIRCHOW, who recalled the meeting to the old and essential definitions of diphtheria (a necrotising process) and croup (an exudative process), and who pointed out the need for a revised nomenclature of such diseases which have been proved to be dependent upon the action of bacteria. For the anatomical term "diphtheria" embraces far more than the disease evoked by the diphtheria bacillus; and a croupous exudation may be caused by the latter as also by other agencies. He urged the necessity of having botanical terms applied to distinguish these different organisms, so as to avoid the confounding of conditions which were etiologically or anatomically dissimilar. In his reply, Professor BAGINSKY maintained his position, and held that the difficulties of the method he had desired to introduce into practice had been over-rated. Of its importance he was convinced, since it was obvious that at least two totally different affections were liable to be included under the head "diphtheria" so long as reliance was placed upon clinical characters alone. He mentioned that he had found LÖFFLER'S bacillus in cases regarded as true croup; and that since his paper was read he had confirmed his observations on rhinitis fibrinosa in a third case.

It will be seen that throughout this debate there was a general recognition of the pathogenic position of the bacillus discovered by KLEBS and LÖFFLER, and the acceptance of the corollary that at its onset diphtheria is a local malady. But where opinion varied was as to the absolutely pathognomonic value of the detection of the bacillus, since it may have been present at the earlier period of the malady, but have been replaced by an invasion of septic organisms subsequently. The discovery of the bacillus in membranous rhinitis was a new fact, and, as all concurred in the mild clinical course run by that affection, this discovery is hard to reconcile with what is known of the virulent character of the bacillus in question. Nor, interesting as his suggestion is, do we think that the method which Professor BAGINSKY desires to introduce into ordinary practice—as an aid to diagnosis—is likely to prove of much value, owing in part to the technical skill and knowledge requisite to obtain the cultures and identify their nature, and in part to the valuable time occupied in obtaining them.

THERE is only one serious disease of horses which is communicable to man, and which for this reason, if for no other, we have an interest in seeing diminished or suppressed. This is the specific eruptive fever called "glanders." Though it has been known as affecting solipeds from the earliest times, yet, strange to say, it was not until this century was well advanced that its transmissibility to the human species was discovered; and in this direction the observations of ELLIOTSON in this country, and RAYER in France, were of great importance. Their conclusions have since received ample corroboration, and now it is a well-recognised fact amongst medical men and veterinarians that the malady can be conveyed to man, and in a more or less virulent and dangerous form. In him it is not invariably fatal, as it is in the horse sooner or later, for cases of recovery in the human subject are on record; but it is, nevertheless, a very grave disorder, and the prognosis must be always doubtful and serious. Though special to equines, it can be conveyed to many other species of creatures besides man, the ass being particularly susceptible, and the ox altogether insusceptible.

Glanders is very much less prevalent than formerly. In the pre-railway days, when horses were so extensively employed in road traffic of all kinds, it was a veritable plague, and there were few stables in which it did not exist. Horses suffering from it were regularly worked, and in the cavalry and artillery corps it was extremely rife. It occasioned great losses in horse establishments, and there can scarcely be a doubt that many people must have died from it, though its nature in them was not suspected. Indeed, its contagiousness in horses was not universally recognised until the beginning of this century in England; while in France it was only about the middle of the century that chronic glanders was acknowledged to be transmissible from horse to horse. As a consequence, precautions were seldom adopted to check the contagion, and curative measures were usually preferred to those of a preventive kind. It was also supposed to be of spontaneous origin, and ascribed to all sorts of influences. But, with the

Digitized by Google

progress of veterinary medicine and better notions of horse sanitation, a great change has been effected in the prevalence of glanders. It has been for some years banished from our military stables, and only exists to any considerable extent in some of our large cities, while believers in its spontaneity must be few indeed and are certainly out of date.

It may, however, be considered doubtful whether all the cases that occur are reported; as, though this is one of the disorders included in the Contagious Diseases (Animals) Act, yet there is reason to think that, from the way in which it is dealt with, it is more prevalent than the annual reports issued by the Government would lead us to believe. However this may be, it would appear that in 1891 only 1357 outbreaks were reported for Great Britain, though this number was much in excess of that in 1890, when it was 937; in the former year the number of horses involved in these outbreaks was 2315, and 2064 of these were in London.

Of late years there has been a gradual increase in the proportion of outbreaks, and it is probable this will go on until the law relating to glanders is amended and more rigorously carried into operation. There is no reason whatever why it should not be extinguished and kept out of the country, provided always that infected horses are not allowed to be imported. One reason why the malady has not been extinguished or reduced to very much smaller dimensions than at present, may be found in the circumstance that, in the Act, glanders and farcy are spoken of and prescribed for as if they were different diseases, whereas they are one and the same, farcy being merely an outward or cutaneous manifestation of the disorder. In the days of farriery, glanders was one disease, farcy was another, and each was submitted to its own kind of treatment; but modern veterinary medicine recognises no distinction, farcy being merely external or skin glanders. This mistake in the Act has had a mischievous effect in perpetuating the disease, as it has recognised a difference in the sanitary police measures applicable to it; for the authorities who carry out these measures are only allowed to kill horses which are glandered, while those affected with farcy may be permitted to live, though they are just as dangerous to other horses. It is somewhat extraordinary that the law has not been amended long ago, and this obsolete notion got rid of; as it can scarcely be doubted that it is chiefly to blame for the maintenance and extension of glanders. Another weak point in the Act, and one for which there can be no tangible reason, is the long lapse that must take place—twenty-one days—after a horse has been declared affected before it can be lawfully slaughtered, though it may be so situated as to endanger the lives of many other horses during that time. The Act should be amended, and brought into harmony with present knowledge of the malady, especially in view of the increasing prevalence of glanders; and as it exists in only a few centres it ought to be easily extirpated from them. It does not require the severe measures which are now in force with regard to bovine contagious pleuro-pneumonia; indeed, they could not be imposed without great hardship. When a case of that malady is discovered on a farm or in a dairy, no matter how many the stock may be, all are slaughtered and the place is declared infected. Glanders exists chiefly in large studs of horses; to kill all these because one case of disease was detected would be most serious and quite uncalled for. It was not in this way that the army was freed from glanders, but by careful inspection, isolation, and destruction of those discovered to be diseased. In contagious pleuro-pneumonia compensation is allowed for the healthy cattle which are destroyed; in dealing with glanders this should not be necessary, for several reasons, but particularly because healthy horses should not be killed, and there are certain inoculation tests that can be resorted to in the case of those which present suspicious symptoms. The principle of compensation is liable to abuse, and there would be the greatest tendency to this if it were applied to glanders. It should be made the interest of the owner to rid his stables of the disease as quickly as possible; to give him a monetary interest in having it on his premises would lead to remissness, and in some cases probably to fraud.

It must not be overlooked that so long as horses are imported from countries in which glanders is present—and there are none in our hemisphere in which it does not exist—we shall always be exposed to its reappearance after it is stamped out, unless the entrance of these horses is entirely prohibited, as cattle now are from infected regions. And even then, in case of a continental war, our mounted corps, though taking the field with a clean bill of health, would not remain free for long; as remount horses must be purchased in other countries, and, as during the Crimean War, these would carry infection with them. The question of glanders, of course, interests everyone more or less; but the fact that it can be conveyed from diseased horses to mankind endows it with a special interest for members of the medical profession, and this will be greatly increased if horseflesh ever comes into use for human consumption in England, as it has done in nearly every European country.

ONE of the electrical journals in the United States, the *Electrical Age*, is very angry with us for our denunciation of what is called "electrocution," and demands of us where we collected our information so far away from the scenes of the decivilising exploits. We can assure our contemporary we spoke of nothing that did not come to us in the way of common information from published American sources, as well as from our own correspondents, and that our comments do not vary a jot from what they would be if the same kind of exploits of "electrocution" were being enacted in this country. And now we have something to say that does relate to something here. We are threatened with a new professor. Mr. BERRY, who calls himself "the executioner for England," has resigned his post, and, turning away from the late field of his operations, is betaking himself to another platform, from which he is about to orate against capital punishment. Until we have heard what the new professor has to say publicly on this topic we can of course express no opinion on his views; but there is another point connected with his change of occupation on which we must have a word. The prevailing opinion is that Mr. BERRY leaves his old vocation because the gaol surgeons have been directed by the Home Office to instruct him in his duties and tell him each time he officiates what length of rope

Digitized by Google

and what drop he is to employ. This, it is said, he resents as an interference with his professional duty. He has learned an art by experience; why should a man who has no experience of the art interfere with him? Why, indeed? Mr. BERRY, from his professional view, has a strong case. But is it true that the Home Office has tacked this new amateur task on to the work of the gaol surgeon? If it be so, we trust that gaol surgeons will tell the Home Office it is no part of their business to direct executions; that they have had no practical experience in the matter, and that the theory involved in it is too uncertain for them to take any part in it. It is, perhaps, their business to stand by and see that the condemned person is actually killed, but for them to be responsible for the details of the execution means a responsibility shamefully imposed, and to be resisted at every step. Suppose, by the direction of a surgeon, a criminal who was brought to be hanged were decapitated owing to some miscalculation on the part of the medical official; or suppose a man hanged were to come to life again after being cut down. These events, and worse, have happened, but, being attached to the executioner have been accepted by that functionary as a sad and unavoidable part of his office. Let, however, the blame rest with a medical man holding a respectable position in society, and what would be his fate? There cannot be two opinions upon the matter. He would be from the moment a marked and avoided man. His knowledge would be impugned; he would be charged with the offence of holding for gain an office for which he was unfitted; terms of obloquy would be attached to his name; and his family, as well as himself, would be liable to ridicule which it would take two generations to wipe out. More than this, if such a rule be enforced, the gaol surgeon will be at everlasting conflict with the executioner. Mr. BERRY resigns in what people will call "cool blood," when there is no particular issue at stake. Another executioner may not have professorial distinctions and good fees therefrom staring him in the face; but, content with his own work, may strike on the spot at a critical moment, and, refusing to accept the surgeon's length of rope, may tell that learned officer to do the job himself and take the consequences. The dilemma is easily conceivable, and would doubtless quickly have occurred if executioner BERRY had not betaken himself to what he considers a nobler and more remunerative vocation. This unpleasant event may therefore be for a time averted; but, if it be not, wranglings between the surgeon and the hangman are inevitable—a most unbecoming conflict. The subject altogether is one on which it would be advisable for a medical voice in the House of Commons to ask a question relating directly to the interests of a large body of highly qualified and conscientious professional men, charged already with duties sufficiently responsible. Since the above was written we have received from a prison surgeon a letter, which we print in another column, and which argues in the same direction as that taken by us in the foregoing remarks.

ON Thursday, the 3rd inst., a most important deputation waited on Lord SALISBURY at the Foreign Office, and laid before him the various objections to the Charter of the Gresham University, now before the Houses of Parliament. The numerous dissentient bodies were all represented—viz., the Victoria University, with its Manchester, Liverpool, and Leeds Colleges; the provincial medical schools of Birmingham, Bristol, and Sheffield; the University of London, and the various teaching bodies in London interested in the different forms of higher education in the metropolis. Although Lord SALISBURY pointed out that the deputation was very late in making their objections, and that they should have been placed before the committee of the Privy Council when the application for the Albert Charter was before that body, it is evident that the Government has every desire to meet the views, so far as is possible, of the objectors, and it has therefore been decided, as Mr. BALFOUR announced on Monday last, to remit the Draft Charter for reconsideration. We understand that this means a reopening of the case before a Royal Commission, where the various dissentient bodies will have to appear by counsel. This means a delay of at least twelve months, and a rehearing of all the parties interested. The objections in respect of the Faculty of Medicine which were placed before Lord SALISBURY by Earl SPENCER, Vice-Chancellor RENDALL, and Mr. CHAMBERLAIN, are, practically, that some of the London schools of medicine do not possess a complete equipment for all the branches of scientific teaching allied with medicine; that there is nothing in the Charter to enforce a sufficient standard of attainment in arts and science for the medical degrees; that the medical authorities will be able and intend to lower the standard for medical degrees; and that the requirement compelling students who migrate from other Universities to reside for at least the final two years in a London medical school will injure the clinical teachers in the provinces. We do not think it would be difficult to meet these objections, but we can quite see that the formation of a strong Teaching University in London may temporarily injure those provincial medical schools which have no power to grant degrees, and it is on this account that we so strongly advise the formation of a Midland University as well as a Teaching University in London. Unless degrees can be given on equitable facilities to medical students at Birmingham and Bristol, those provincial schools will gradually lose their students, as has for some years been the case in London, and this will take place whether the Gresham University be established or its promoters be defeated. The Provincial and Scotch Universities are now attracting an increasing number of students from the midland counties as well as from the metropolis. The answers to the objections raised by the members of the deputation who referred to the medical question are that sufficient science teachers and schools exist in London to permit of preliminary science being carried on efficiently in them, so that those schools which desire to be clinical and to give up the preliminary scientific training can easily do so; that there is no intention of lowering the standard in arts and science (this has been expressly stated by Professor ERICHSEN, Sir GEORGE YOUNG, and the Deans of the London Medical Schools, whose statements were altogether ignored by Mr. CHAMBERLAIN); and that the two years' "final" clause was insisted on, in its own interest, by the University of London. But we see no reason why any other two

Digitized by Google

years should not be allowed, as in the Charter of the Victoria University itself and in the Scotch Universities. We hope that some workable plan will be arrived at whenever the case comes to be reheard. The Victoria University can grant degrees to Manchester, Liverpool, and Leeds medical students on fair terms, and it is a grave injustice that London should be debarred from a similar privilege. With regard to the question of higher education in London, which is now so interwoven with the medical problem, we can only express, with Lord SALISBURY, the wish that whether the Houses of Parliament finally decide on a positive or a negative action, after such modifications are made in the Charter as may be determined by the Royal Commissioners, "it will not be such, on the one hand, as to put a stop to the development and growth of this question, and, on the other hand, that if it takes a positive character, it will leave the door open for the introduction of such improvements and extensions as shall bring together all the educational power and all the educational enthusiasm of this metropolis in the common search after one end."

Annotations.

"Ne quid nimis."

THE PREVENTION OF SMALL-POX.

AN important communication was made to the last fortnightly meeting of the Metropolitan Asylums Board, held under the presidency of Sir E. Galsworthy. It related to the maintained freedom of the metropolis from small-pox, a freedom which has gone hand-in-hand with the prompt removal of small-pox patients out of London. It is well known that, owing mainly to Mr. W. H. Power's investigations, it was ascertained that the aggregation of small-pox patients in London hospitals led to the diffusion of the infection to the population around; and it is certainly most significant that since this practice has been abandoned London has experienced an unexampled freedom from small-pox, and that, with but few exceptions, the provinces heretofore attacked in sequence to metropolitan small-pox epidemics have experienced a similar freedom from the disease. The result bears out the views expressed by the Medical Department of the Local Government Board in this matter, and it is now authoritatively announced by the Metropolitan Asylums Board that the continuance of this policy of prompt removal from the metropolis for isolation purposes is essential to the safety of London. Another point which was brought under the notice of the meeting had to do with the scattering of responsibility concerning infectious diseases amongst different authorities. Taking small-pox as an example, it may be noted that isolation is carried out by the Asylums Board, disinfection by the vestry, and vaccination by the guardians. The report, which was communicated to the meeting, pointed to the desirability of unity of administration in these respects, and it was suggested that if the Legislature were to hand over to the Asylums Board the duty of seeing to vaccination and revaccination an important gain would result, especially by way of promoting the needed operations for prevention at the earliest possible moment. When it is remembered that Sir E. Galsworthy is at the present time a member of the Royal Commission on Vaccination, this utterance appears significant of views that may come to influence the report of that Commission in respect of modifications in the existing practice and administration of vaccination.

THE LONDON COUNTY COUNCIL.

THE very considerable interest taken in the election of the new London County Council is full of promise. We are not concerned in any question whether "Progressives" or "Moderates" should have the ascendancy, but we hail with satisfaction the fact that Londoners recognise the importance of a satisfactory government of the metropolis. The last Council devoted itself assiduously to its public health duties, and, so far as its powers permitted, encouraged in every direction a more active health administration. Apart, therefore, from any thought as to whether Londoners should return Conservatives or Liberals to manage their business, we are glad to find many members of the old Council remaining to continue the work they have begun. In a few cases the vote of the electors has deprived London of the services of men who deserved a better fate, and in others active and useful members have not submitted themselves for election. With regard to the former, we sincerely trust that the Council will exercise a wise discretion, and will by electing them aldermen secure a continuance of the good work they have done in the past. The Progressives have so large a majority that they need have no concern for the consideration to which party these members belong. It is the interest of the dominant party to show that London, vast as it is, is able to administer its own affairs, and this party will be acting wisely if its choice fall upon those who are certain to make its administration as useful as possible.

Among the representatives who have at the recent election been returned to serve on the London County Council for the ensuing three years are a proportionately small number of members of the medical profession, some of whom have already done useful service in the capacity of councillors. The names of Mr. W. Gibson Bott (West Newington) and Dr. G. B. Longstaff (Wandsworth) will be recalled in this connexion. Dr. W. J. Collins (West St. Pancras) and Mr. J. T. Macnamara (Rotherhithe) are the only new medical County Councillors. Mr. Bradenell Carter, the former member for West Islington, did not seek re-election, and one or two medical practitioners who sought the suffrages of the electors were, unfortunately, unsuccessful in their candidature.

MR. STANHOPE ON THE ARMY.

ON Monday night Mr. Stanhope introduced the Army Estimates by a long statement in the House of Commons. Owing to the controversy that has been going on about the state of the army, and all that has been written concerning military matters, to say nothing of the recent publication of the report of Lord Wantage's Committee, the occasion was looked forward to with an unusual amount of interest and curiosity. The War Minister's speech was long and lucid, and optimistic in tone. Mr. Stanhope evidently gave his mind to the task, and traversed the whole controversial field, alleging that he had approached each debateable question with an open mind. The subject, however, is far from closed, and later on much in the way of sharp criticism and discussion may be expected. Speaking of the army in India, Mr. Stanhope gave some interesting information on the relative health statistics of a long and short service system. Comparing the figures for two periods, he showed that the annual average mortality was 25 and the invaliding nearly 44 per 1000 for the long-service period, while the figures were respectively 15·5 and 23·5 for the short-service period. This does not, however, prove conclusively that the inefficiency from sick-

Digitized by Google

ness is less under the short-service system, although it does undoubtedly show that the invaliding and death rates are much less. Mr. Stanhope, speaking of the Army Medical Department, the strength of which had been carefully reconsidered, said that considerable reductions had taken place. He alluded to the employment of civil practitioners, the growth of an Army Medical Reserve, and dwelt upon the time that had been devoted to the arrangments necessary, in case of mobilisation, for the medical services in *personnel* and equipment. What with the new Lee-Metford magazine rifle, an improved system of artillery, and smokeless powder, the next big war is likely, we should imagine, to strain the powers of a medical service to the utmost. With regard to the increased barrack and hospital accommodation and the sanitary services projected or already carried out, Mr. Stanhope looked forward to the beneficial results that would accrue from expenditure in this direction. In connexion with this subject he expressed himself as well satisfied with the work done by the Army Sanitary Committee.

THE LONDON WATER-SUPPLY.

DR. FRANKLAND reports that the water abstracted from the Thames in January by the Chelsea Company was much inferior as regards organic impurity to that delivered by the same company in December. The water supplied by the other Thames companies was, on the other hand, of much better quality in January than in December, the most marked improvement being observed in the water of the Southwark and Lambeth companies. All these waters were efficiently filtered before delivery. The water taken chiefly from the Lea by the New River Company exhibited only a slight improvement over the sample taken in December, whilst that sent out by the East London Company was not quite so good. Both these supplies were inferior to the best of the Thames waters. They were efficiently filtered before delivery. The quality of the water-supply during January has distinctly improved, according to the report of the three experts, Dr. Odling, Dr. Tidy, and Professor Crookes, who state that "except for the occurrence in three instances of but 'very slight turbidity,' the condition of the water-supply to the metropolis during the month of January was entirely satisfactory.'

PRESCRIBING BY TELEGRAM.

OBJECTIONABLE and dangerous as is the practice of issuing medical prescriptions by means of the press, or by letter, it may well be questioned whether the employment of the telegraph for the same purpose is not still more open to misuse. Novel and of more than doubtful expediency, this custom nevertheless is not unknown. A case was lately reported in the daily press in which a patient thus received by wire instructions wherewithal to provide himself with physic. Thus furnished, he was somewhat annoyed to find that hardly any druggist could be induced to execute the informal mandate of his medical adviser. We do not wonder at this, and the less so that poisonous ingredients were included in his "order." Cases of this kind expose the patient and the practitioner likewise to more than one difficulty. There is first the delicate point of diagnosis. How is a medical man to understand and correctly treat ailments of which he has, except from a mere statement of subjective symptoms, no present—and, therefore, no certain—knowledge? It may be said, indeed, that previous examination will often afford a reliable clue, and, to some extent, this is true. Chronic states are doubtless in this respect quite different from more acute ailments, and their features are appreciable in proportion to their character and duration. Still, even in such cases the best results and the least anxiety must ever accompany a personal interview. As for medical treatment by promiscuous advertisement, this is nothing less than immoral. Returning to the telegram, however, we find in it yet another element of danger in that it affords no reliable guarantee of correct statement. The prescriber's expressions may easily be misunderstood or misstated by the officiating clerk, thus committing the dispenser, if he will, to a matter of guesswork, and that perhaps in circumstances of critical importance. The druggist in such a case has no ready means of reference or amendment, his salutary influence as a check upon *lapsus pennæ* is impaired, and the risk of the confiding but too heedless patient is proportionately greater. Clearly, therefore, the wire affords no suitable medium for professional prescription, and its employment, even where it does not prove a means of mischief, is at least a serious error of judgment.

NOTIFICATION FEES.

THE Ebbw Vale Board of Health at a recent meeting betrayed much dissatisfaction with the payments due to their excellent medical officer, Mr. J. W. Davies, under the Notification Acts. They appointed a deputation to wait on this gentleman to urge him to reduce his legitimate charges. The deputation seemed to shrink from so unreasonable a request, but one of its number was more courageous. Mr. Davies objected to act differently from his neighbours. One member of the board was for abandoning the Act, but was firmly informed by the clerk that that was not possible. Another thought that the high mortality of the district was a reason for lowering the fees, an argument which we fail to see. In the end, the board appointed the medical officer for only six months, with a threat to advertise for another. This is highly discreditable conduct towards a creditable officer. The *Tredegar and West Monmouth Times* has evidently a high respect for Mr. Davies, but a low opinion of the framers of the Act, which it characterises as another instance of the bungling and incomplete legislation of a Tory Government. Mr. Davies should disregard the threat of his board, and appeal for protection to the Local Government Board.

MEDICAL LITERATURE.

A PURELY commercial view of medical literature has been put forward in a leading article in the *Author*, the official organ of the Incorporated Society of Authors, conducted by Mr. Walter Besant, and, if the article is to be believed, medical literature, as an investment, occupies a peculiar position in rarely bringing any direct profit and in mostly entailing a heavy outlay. The writer divides medical books into (1) works of general medical reference, (2) books written in one of the popular series, (3) monographs on special medical subjects. It is admitted that the first and second classes may be financial successes, but in both the success seems to be rather that of the publisher than the writer. Books written as parts of a series pay the author by bringing in some money and some reputation. The good books of a series sell the bad ones, and the popular prices suit the purses of a great many people. The actual amount of remuneration received by the author is mostly small, but the work is undertaken, according to the writer, partly with a view to fame, and partly perhaps for the sake of not being crowded out of the field by some other person equally fitted for the task. The third class, however, the monographs on special medical subjects, is the one whose unique position seems most interesting. The chief difficulty is of course that when an expensive book has been produced the circulation is extremely limited and necessarily entails loss. A few *savants*, a few professors, and a few libraries purchase the book, and by these the knowledge is disseminated in lectures, comments, reviews, and scientific articles. The reward is in-

Digitized by Google

direct, and is supposed to come in the form of appointments, pupils, lectureships, practices, and "legitimate notoriety, with its substantial results.' Although there is a certain amount of truth in these remarks, the way in which material for the book is to be gathered seems to be curiously ignored. Mostly "appointments" have preceded the publication of the book and have furnished the experience, which has gradually crystallised into new theories or new aspects of the subject; indeed, unless this is the case, it is to be feared that the author has been engaged on the profitless task of endeavouring to make bricks without straw. Still, there can be no doubt that books on special medical subjects published on commission do not and cannot pay the author by their sale. Whether the "legitimate notoriety and its substantial results" are always quite as legitimate and quite as substantial as the writer of the article appears to believe may be open to doubt. The laws which govern the growth of fame and of practice are so subtle that they elude definition, and their uncertainty has to be faced by all who feel tempted to try the effects of an investment "on commission."

COKE OVENS AS SHELTERS.

IT is difficult to picture a condition more strikingly illustrative of destitution than that which has lately attracted the attention of the Durham sanitary authorities. We refer to the practice of allowing disused coke ovens to be occupied for human habitation. According to recent information one such oven constituted a domicile for eleven men, while a number of poor creatures lay and slept, or appeared to sleep, on the roof and sides of this extraordinary bed chamber. We may take it for granted that the fires of these extinct volcanoes had long before become cold, otherwise there would not have been wanting a record of fatal consequences from inhaling their poisonous atmosphere. It is conceivable, however, that an oven which had not quite cooled down may occasionally have been used as a shelter, its remaining warmth constituting a seasonable attraction, its lingering carbonic fumes a deadly and insidious peril. In order to develop the causes of mischief, however, not even this condition is needful. The air of a small and confined space in which a number of persons are sleeping cannot be of the purest, since the mere act of respiration must very soon produce a dangerous excess of carbonic acid. We must, therefore, while we pity those who are expelled from even so cheerless a shelter, approve the action of the local sanitary board, who have requested colliery owners to deny access to their ovens for sleeping purposes. It is evident, however, that a further duty remains for the board and the parochial authorities—namely, to afford to these evicted outcasts as far as possible some alternative and more wholesome protection against the weather.

NERVOUS SEQUELÆ OF INFLUENZA.

WHEN a storm has swept across a tract of country, although the bulk of the damage which it has done may be visible at once, there are many of the effects of its violence which do not immediately obtrude themselves. Trees may have been shattered and buildings wrecked, growing crops may have been ruined and live stock destroyed, but its ravages do not stop there. This country has recently been exposed to the full force of a severe epidemic—an epidemic which the obscurity of its origin and the suddenness and severity of its attack have combined to render even more alarming than others with which our acquaintance is greater, we cannot say closer. The full force of the epidemic has now, it may be hoped, spent itself. But as the storm leaves behind it trees which are blighted but not destroyed, so this disease, apparently so trivial, seems not rarely to be succeeded by conditions of nervous exhaustion and depression, to combat which requires all the art and skill which knowledge and experience can suggest. There seems to be little reason to doubt that the poison of influenza has a special influence on the nervous system. Numerous sequelæ of the disease have been described affecting the nervous system in its various parts, both central and peripheral; and there are not a few who hold strongly the opinion that in all its manifestations, both primary and secondary, it is essentially a nervous disease. But whether this view be correct or not, it will scarcely be questioned that the disease gives rise to symptoms of nervous disturbance, both widespread and severe. In estimating the amount and the frequency of such disturbance, allowance must of course be made for errors of observation. No doubt there has been too much tendency lately to ascribe morbid conditions of various kinds to a precedent attack of influenza, and this disease, already sufficiently loaded with its own burden, has been made to bear a share of others from which it had a right to claim exemption. Thus a patient may date the commencement of symptoms which now clearly point to cerebral tumour from an attack of influenza, but careful inquiry may elicit the fact that the only evidence of this was an attack of headache and vomiting, probably the first attack of this character associated with intracranial growth. So also, no doubt, with other conditions; but even after making a liberal allowance for such errors on the part of the patient or other observer, a considerable residuum is left in which one is driven to acknowledge an incidence of cause and effect; and if this is true of actual structural change in the nervous system, it is no less true of the serious and alarming conditions of what is known as functional disorder, which may go on to manifest itself in profound mental alteration. The excessive depression and lassitude which follow an attack of influenza are too familiar to require more than a mere mention, and in highly neurotic patients such a condition is often quite sufficient to upset entirely the somewhat unstable mental equilibrium. This was no doubt the case with a poor woman who a few days ago was found sitting on her kitchen floor in front of the fire tugging at a clothes line, which was twisted round her neck. Upstairs her two children, one a boy of two and the other a baby of six months, were found strangled. Evidence was to the effect that, although previously a healthy woman and living happily with her husband and family, she had become much depressed after an attack of influenza, and this depression had apparently been succeeded by mental derangement. Many similar cases are on record, and they show the profound effect which the poison of this disease has upon the highest nervous centres.

A NEW WEAPON AGAINST MEDICAL ADVERTISING IN THE UNITED STATES.

IT is well known that in all the more enlightened parts of the United States there is a creditable effort to elevate the medical profession by legislation that shall secure the better education of its members, a due examination of them or of their credentials, and the advantage of certain privileges. Such legislation to be complete must provide means for enforcing some discipline by which medical men are to be distinguished from unbridled and unprincipled quacks who prey on the sufferings and credulity of the ignorant. A Bill before the General Assembly of Ohio not only creates a board for examining all persons desirous of practising in the State, but contains a penal clause which provides that every travelling physician must pay for the privilege of practising the sum of twenty dollars a day for the entire time that he shall remain in each town, under a penalty of from fifty to a thousand dollars fine and imprisonment. We gather from the newspapers which object to this

Digitized by Google

clause that it is meant to meet the case of "regular" physicians who itinerate, and "sound a trumpet before them" as other deceivers of old did, and after staying just long enough in a place to extract the money of the deluded, pass off to another town to repeat the same discreditable charlatanry. Such tactics are the resource of dangerous nd unprincipled men, whom every reputable College would be ashamed of. Without committing ourselves to this exact form of punishment, we heartily approve of clauses for giving to a rightly constituted Medical Board the power of dealing with a great public evil.

EXAMINATIONS FOR ADMISSION TO THE ARMY MEDICAL DEPARTMENT.

WE briefly alluded last week to the fact that at a Comitia of the Royal College of Physicians, held on the 3rd inst., the report of the delegates appointed by the Royal Colleges of Physicians and Surgeons to consider a letter from the Secretary of State for War in reference to the examinations for admission to the Army Medical Department had been read and adopted. The delegates were Mr. Thos. Bryant, F.R.C.S. (chairman), Sir Joseph Fayrer, M.D., K.C.S.I., Dr. Cheadle, Sir Dyce Duckworth, M.D., Dr. T. Henry Green, Dr. Farquharson, M.P., Dr. Norman Moore, Sir William Savory, Bart., F.R.C.S., Mr. J. W. Hulke, F.R.C.S., Sir William Mac Cormac, F.R.C.S., and Mr. N. C. Macnamara, F.R.C.S. The delegates recommended the Royal Colleges to reply to Mr. Stanhope that the two Colleges were willing to undertake the conduct of the examinations, subject to the conditions that the examinations were under the control and management of a committee consisting of representatives of the War Office, the Royal College of Physicians, and the Royal College of Surgeons; that the examiners be nominated by the committee and appointed for a definite period by the two Royal Colleges; and that every candidate shall be examined in each subject by two examiners in conjunction. In the event of these conditions being accepted by the Secretary of State for War, the delegates recommended the immediate appointment of the committee, with a view to their drawing up a scheme of examination for the consideration of the War Minister and the Royal Colleges. It seems to us that this is, on the whole, a step in the right direction, which will commend itself to the profession. The appointments of examiners should be for fixed and definite periods, and not life appointments.

POISONING BY ROBURITE.

WE have in our columns on several occasions reported cases of poisoning by roburite, and have also given prominence to the inquiries and investigations of Professor Harold Dixon, F.R.S., Mr. Hannah and Mr. Mounsey; also of Professor Bedson, Drs. Hume and Drummond of Newcastle. The conclusions of the latter gentlemen were to the effect that the products of the explosion of roburite and tonite are not more deleterious than the products of the explosion of gunpowder. Last week Mr. Butcher, one of the coroners for Lancashire, held an inquest on a man named Sandsland at Atherton, near Manchester, whose death was said to have been caused by meningitis induced by the inhalation of fumes from an exploded roburite cartridge. This appears to have been the opinion of Dr. Martin, who had attended the deceased during his illness, which lasted three days. The fireman who fired the shot had also been in the place after the explosion, but complained of no ill effects. The coroner, recognising the importance of the inquiry, adjourned it, so as to obtain scientific evidence on the point. Professor Paul, F.R.C.S., of University College, Liverpool, was engaged, and he examined a portion of the deceased's lung, a kidney, and a piece of liver for nitro-benzine, also some of the blood spectroscopically for carbon monoxide; in both instances negative results were obtained. He further stated that from negative results it does not necessarily follow that such poisoning had not at some time been present, because these poisons are volatile and may have passed out of the system. Being further questioned as to accepting the cause of death as meningitis, he was of opinion it was due to natural causes. The jury returned a verdict, however, that the deceased died from inflammation of the brain and membranes of the brain, and that such inflammation arose from his having by accident inhaled certain noxious gases liberated upon the explosion of a roburite cartridge, and came by his death by accident, and not otherwise. Our readers are familiar with the curious findings of jurymen. Often the profession, or rather individual medical men, meet with censure most undeservedly at times from twelve intelligent jurymen; but in an inquiry like this it is impossible to remove from our minds the fact that if a pitman meets with anything which causes death that can be construed as an accident, his friends participate in the allowance made by the Miners' Permanent Relief Society, and it is no uncommon thing in colliery districts for even the most trivial injury which has occurred months before to be blamed for what is really due to natural causes.

THE MANCHESTER AND SALFORD PROVIDENT DISPENSARIES ASSOCIATION.

THE annual meeting of this Association was lately held in Manchester, and the reports were considered by the promoters to be pretty satisfactory. They congratulated themselves that 1300 members of clubs were connected with the dispensaries, or 159 more than in 1890. We cannot regard this as a matter for much satisfaction. Clubs and friendly societies can take care of themselves, and the promoters of friendly societies would do better to cater for those who cannot do so. The amount of members' subscriptions for the year was £4183, of which sum only £2563 found its way to the medical staff. An attempt to increase their pay by charging three halfpence instead of a penny for medicines was unsuccessful. An ungracious attempt to make the notice for terminating medical appointments three months was much resented by the medical men. One practitioner, in a letter, said that if this were carried his resignation would follow. Not only that, but he would "expose the so-called philanthropy of your council, who make the medical men the scapegoats of your vicarious philanthropy," and he would take care to enlighten the public with regard to the feeling which existed in the council towards the medical staff. After a further protest from other medical men the motion was withdrawn. The most creditable boast of the Association is to have reduced hospital abuse from 42 per cent. to 6 or 7 per cent. by coöperation between dispensaries and hospitals.

"CHEMOTAXIS" VEL "CHEMIOTAXIS."

AS science advances and new ideas spring from new observations, fresh terms have necessarily to be employed to denote phenomena that have previously passed unnoticed. But investigators who employ such terms should be careful to see that they are well understood by those who listen to expositions or peruse writings which contain them. It is in the interest of the many who desire to have a clear comprehension of the knotty question at present dividing the pathological world that we would invite the next "phagocytist"—another new term (!) necessitated by the struggle that is now in progress—who speaks in the debate at the Pathological Society to condescend to state explicitly the precise etymology of the phrase that lies at

Digitized by Google

the root of the controversy, and concerning the spelling and pronunciation of which there seems to be as great a difference of opinion as there is between the two opposing camps on the main question. Of course, it may be said that it does not matter an "iota" if that useful little vowel be omitted, and the word of five syllables degraded to one of four; but there must be some reason for its retention in the minds of those who do retain it, or for its rejection in the minds of those who discard it. Nor is this all. The ordinary man would like to go a step farther, and ask the expert how the two parts of this compound word hang together. By a stretch of imagination he can conceive that "taxis" may imply the marshaling of the phagocyte forces to resist the invader; but then the chemical influences which he may suppose to be denoted by the first root are considered to act either "positively" in attracting or "negatively" in repelling the martial leucocyte. So that "taxis" cannot be used in its classical sense. It is, perhaps, unfortunate that the discovery that some substances attract and others repel leucocytes (the term "chemotaxis" was in the first instance, we believe, applied to micro-organisms should have led to the use of the adjectives "positive" and "negative." But we suppose there is no help for it now. Only it would be satisfactory to know how this important word is to be spelt, especially if it is going to assume a permanent place in pathological terminology. We should like to add also a protest against the lax way in which such words as "immune," "vaccination," and the like are being used by pathologists. For it would seem that the precision with which they conduct their scientific researches is somewhat lacking in their language. Can it be because science is replacing the old-fashioned classical education in primary schools that so little regard is often paid to etymology by scientific men?

MEDICAL STUDENTS IN THE FRENCH ARMY.

CONSIDERABLE dissatisfaction prevails concerning new regulations enforced upon the medical students who are serving their time in the French army. Every medical student, unless he is physically unfit, must serve at least the full 365 days under the flag and in the barracks; but formerly they were allowed to frequent the military hospitals and faculties. Here they proved of considerable service. They took temperatures, dressed wounds, &c., and rendered intelligent and efficient aid. They were popular with the officers, the medical staff, and the soldiers because they were useful to one and all. Now, however, orders are given that medical students are not to be admitted to the military hospital during their term of military service, nor are they to be allowed to follow any medical teaching. The whole of their time must be devoted to drilling, they must shoulder gun and knapsack, and march with the awkward squad. This would be quite right and fair if doctors went into the battlefield as simple soldiers. Students in seminaries training for the priesthood have to serve in the rank and file, and medical students must pay the blood-tax as well as every other member of the community. The only objection is that, though the medical student when he becomes a doctor is, in common with every other Frenchman, liable to military service up to the age of forty, he has his position as surgeon to such or such a battalion assigned to him. When the order comes to mobilise he does not take a gun, but his surgical instruments. Therefore, it is urged, it would be more useful to the army if, during the year he is under the flag and in active service, he were allowed to acquire some experience of military hospital work. To this the War Office reply that every medical student does not of necessity become a doctor, but he must of necessity and without a single exception serve his country in case of war. Therefore in the event of war breaking out before the medical student has become a fully qualified surgeon, the War Department expects to find him fully qualified as a simple soldier. Even when dealing with a well-educated and intelligent medical student, 365 days' constant drilling, rifle in hand, is not too much to make a good soldier. Nevertheless, it is easy to understand that the medical students should protest. It is hard that they have to work very rigorously for a whole year to qualify as simple soldiers when, in the majority of cases, they will never have to serve in that capacity.

INDIAN SANITATION.

SIR WILLIAM MOORE read an elaborate paper before the Society of Arts, Adelphi, on March 3rd in the course of which he said that in no three large cities in Europe had greater advances in sanitation been shown during the last twenty years than in the cities of Bombay, Madras, and Calcutta. This is a very important statement; for if it be true that the history of men is reflected in the history of their sanitation, it contains important evidence of general progress among the inhabitants. Further, on comparing many Indian towns with those in Continental countries between Great Britain and the East, it is found that they occupy a very favourable sanitary position. Those authorities, consequently, who are of opinion that insanitary conditions are necessary to the generation of cholera will not require to search for these conditions so far eastwards as India. It was pointed out that they may be found in greater numbers, and possibly in more noxious intensity, in countries between Europe and India where climatic conditions are more favourable to the development of that disease. Sir William Moore thinks, notwithstanding the fact that cholera is always present more or less in India, owing to the defective personal hygiene of the people, and from other causes, that European epidemics would occur just as frequently if no such condition existed. But Indian sanitation is still young. Much requires to be done to perfect it. "The requirements," he says, "are numerous and should be reiterated again and again." That may be applicable to most countries. There is deep philosophy in Descartes' saying, that if it be possible to perfect mankind, the means of doing so will be found in the medical sciences. Sir William Moore's paper shows very strikingly the amount of progress towards sanitary perfection which has already been attained in India.

THE HEALING OF WOUNDS IN BLOODLESS OPERATIONS.

THE after effects of the bloodless system of operating, as carried out by means of Esmarch's bandage, not having been very satisfactorily ascertained, Dr. Sokolovski of St. Petersburg, working in Professor Ivanovski's laboratory, has recently performed a large number of experiments for the purpose of ascertaining whether under this system the healing of wounds is at all altered or retarded. His plan was to make similar incisions or other wounds on the two hind legs of a dog or a rabbit. One of the limbs had been rendered bloodless by an elastic bandage, while the other was operated on without this precaution. Both wounds were dressed, and their subsequent progress compared both by ordinary and by microscopic observations. The regeneration of epithelial elements is brought about by the multiplication of the cells of the formative layer by indirect or partially direct division. Sometimes the wound becomes covered with an epithelial growth, which is inefficient, not being permanent, but undergoing degeneration. Generally the cells of the old epithelium at the edges of the wound undergo changes consisting in a diminished amount of chromatin, in consequence of which the nuclei are bright and stain badly, or the chromatin fibres become

Digitized by Google

diminished in number, but are shorter and thicker; these changes do not, however, go as far as chromatolysis. Mitoses of the epithelial cells are mostly seen when the wound is covered with one or two layers of cells; sometimes, however, they occur in the cells of old epithelium lying in close vicinity to new cells. All the above processes take place in wounds, whether they have been inflicted on a bloodless limb or on one in its ordinary condition; but in the former case there is a marked retardation. If the bloodless condition of the part has not lasted more than three hours, the alteration in the cells is but slight, and confined to the superficial layer. When, however, it has persisted for a longer period, the cells of all the layers are affected, the nuclei becoming stellate, staining badly, appearing too bright, and having a deficiency of chromatin. The mitoses are diminished in a wound made in a bloodless part, and some of the karyokinetic figures are abnormal, the rays of the asters being irregular or shortened and thickened.

ETHER AS A STIMULANT AT THE TEMPERANCE HOSPITAL.

A CORRESPONDENT of a contemporary expresses surprise that at a public meeting at the Temperance Hospital it was announced that the internal use of ether is allowed in the hospital in place of alcohol. We cannot think that there is much to justify this difference. Ether drinking is a vice which has but lately in Ireland assumed grave proportions, requiring special legislation. It is affectation to regard the use of such an agent as morally or physically better than the use of approved forms of alcohol. By all means let the physicians of the Temperance Hospital cure disease—where they can do so equally well and equally quickly—without alcohol. Such treatment is instructive, but where some form of diffusible stimulant is needed, to prefer ether to alcohol is scarcely the way to promote temperance.

OVERCROWDING OF THE PROFESSIONS IN THE COLONIES.

THE *Sydney Morning Herald* has lately published an interesting series of articles on the overcrowding of the profession in New South Wales. It is difficult to get at perfectly reliable data for a medical census. Chiefly because there is no satisfactory means of ascertaining the number of deaths among the registered practitioners or of the removals from the colony. But taking all possible precautions and using the best means to arrive at an approximately accurate conclusion, our contemporary's special correspondent estimates that whereas in England there is one medical man to 1562 persons, there is in New South Wales, and perhaps other Australian colonies, one medical man to 1890 persons. There are in New South Wales about 600 qualified practitioners to a population of 1,134,207. We confess to being rather doubtful of statistics from registers on which it is believed that dead men figure year after year, and others are regarded as dead on very insufficient evidence. The estimated income of medical men in the colony of New South Wales is calculated to make us dissatisfied with our modest emoluments. Several leading practitioners in Sydney have an income of £6000 a year, and the average income of the medical practitioner is considered to range between £1000 and £2000. We should enjoin on our young readers a little wholesome scepticism on these calculations, which exceed if not "all Greek all Roman fame," at least all English and probably American experience, and which ill consort with those breaches of professional manners and methods of which we have already written, the best excuse for which, though an entirely inadequate one, is the pressure of competition, largely, it is true, from unqualified practice which rages unchecked. The great thing wanted is an improvement in the means of informing the registrar of the death or change of residence of those registered. Our own Act is not very effective in this respect, but it is much more so than that of New South Wales. There is a Bill now before the Colonial Parliament for perfecting the system of registration, to which we wish every success.

EXPULSION OF A DEAD FŒTUS IN FRAGMENTS.

THE *Wiener Med. Chir. Rundschau* gives an account by Dr. Liebmann of a remarkable case of expulsion of the dead fœtus. It is necessary, he points out, to remember that a dead fœtus may remain in the uterus some length of time. At the second month it may become absorbed or transformed into a mole. At the fourth month it may become either mummified or macerated, either undergo fatty degeneration or calcification, or, in cases of extra-uterine gestation and ruptured uterus, it may escape into the abdominal cavity, to be removed either by the formation of an abscess or by operative interference. It rarely happens that the fœtus undergoes complete decomposition in the uterus and is discharged piecemeal. In the case described by Dr. Liebmann this, however, occurred. The soft parts of the fœtus, which was between the third and fourth month, came away in the form of a sanious discharge from the vagina, attended with slight rise of temperature. Later on the bones, either separately or several at a time, appeared at varying intervals. This continued for some months, the placenta being discharged, at the end of that time, as an oval fleshy mass, the size of a pigeon's egg, with eight bones attached to it.

THE HEALTH OF MALVERN.

THE appointment of medical officer of health to the district of Great Malvern is vacant. The place has a considerable and deserved reputation as a health resort, and it should have a health officer who, by reason of his qualifications as an expert in public health, should inspire confidence with the public and their medical advisers in all parts of the country. And where skilled services are sought they should be adequately remunerated.

PASSAGE OF TUBERCLE BACILLUS FROM THE MOTHER TO THE FŒTUS.

BIRCH-HIRSCHFELD AND SCHMAL[1] have recorded a case which they consider is the first in which it has been definitely shown that in the human subject tubercle bacilli can pass from the mother to the fœtus. The patient was a young woman who, shortly after the commencement of her first pregnancy, began to exhibit symptoms of incipient phthisis; the disease assumed an acute form, and progressed so rapidly that the patient died during the seventh month of her pregnancy. Immediately after the death of the mother the child was removed by the operation of Cæsarean section. A post-mortem examination was made on the body of the mother. Advanced tubercular changes were found in the lungs, and also some miliary tubercles in the liver and other organs. The child had been felt to move after the death of the mother, but by the time the operation had been performed it was found to be dead. The thorax was at once opened, but the lungs appeared to be quite healthy. The body was then removed to the laboratory, the surface of the abdomen washed with perchloride of mercury, and the cavity opened by means of sterilised knives. No evidences of tubercle could be found in any of the organs. Small pieces of the liver, spleen, and kidney were removed with sterilised instruments, and placed in the abdominal cavity of two guinea-pigs and a rabbit. One of the guinea-pigs died in

[1] Beiträge zur Path. Anatomie und zur Allg. Path., 1891, p. 429.

Digitized by Google

fourteen days; miliary tubercles were found in the peritoneum and large omentum. The second one was killed about six weeks after inoculation, and the same appearances were noted. The animal had appeared ill, it was feverish, and emaciating rapidly. The rabbit lived considerably longer—three months; after death tubercles were found in the liver and lung. From these experiments it was evident that although no tubercular lesions could be found in the organs of the child, yet the latter were capable of infecting animals; and had the child survived, it would have undoubtedly developed tuberculosis at an early age. It is a point of great interest to read that tubercle bacilli were found in the umbilical cord and in the blood of the umbilical vein.

INTERNAL ADMINISTRATION OF CHLOROFORM IN ENTERIC FEVER.

DR. P. WERNER of St. Petersburg has treated 130 cases of enteric fever with a 1 per cent. solution of chloroform with the greatest success. His attention was first called to the use of this drug by the investigations of Behring as to the germicide action of chloroform upon the bacillus of typhoid fever, but he was not aware at the time that Dr. Steppe of Nurenburg had used chloroform in 1890. Dr. Werner made use of a 1 per cent. solution of chloroform in water, of which the patients took a tablespoonful every hour or every two hours during the height of the disease, and for some days after the temperature had become normal. In all cases in which this treatment was adopted, before the tenth day great improvement was manifested, and even when commenced as late as the third week benefit resulted. The usual typhoid symptoms did not appear, the tongue did not become brown, diarrhœa and tympanites gradually disappeared, there was no tendency to bedsores, and relapse was very rare. The treatment was in most instances well borne, but in four cases slight jaundice, sufficient to cause a discontinuance of the drug, was observed. Dr. Werner's observations agree with those of Dr. Steppe, and he considers this treatment well worthy of a trial, if for no other reason than its absolute harmlessness.

AN INDIAN FAKIR.

AN account of the "performances" of the Indian fakir Soliman ben Aissa is supplied by our Vienna correspondent. The exhibition has very properly been forbidden in public places in Vienna, but a series of private entertainments has been arranged. An aristocratic audience was present at the first of these, Professor Mosetig Moorhof representing medicine. The fakir commenced his performances by inhaling the fumes of a burning powder prepared from extracts of snake and scorpion poison, and certain quick movements of the head produced a foaming at the mouth. After these preliminaries, needles and other sharp instruments were thrust through various parts of his body, including a stiletto a foot long and half an inch broad, which was thrust through his tongue. Another feat which is said to have caused great sensation consisted in pulling forward the eyeball and presenting it outside the orbit, to the view of the audience, between two fingers. He was "invulnerable" also to the heat produced by a flaming torch held for a minute and a half against the under surface of his forearm. After chewing glass and playing with poisonous snakes the fakir nearly fainted, but speedily recovered his good spirits. The recital of these feats recalls the excitement that was caused in London many years ago by the similar so-called "experiments" of M. Chaubert, the renowned fire king, who succeeded to all appearance, in defiance of all laws, chemical and medical, in drinking poisons and swallowing hot irons and boiling lead, amid the enthusiasm of a large portion of the British public. He succeeded only for a time. The history of his exposure, sudden downfall, and subsequent malignity forms perhaps one of the most interesting and humorous passages in the older volumes of THE LANCET. The fire king had boldly advertised that on a certain occasion he would take a large quantity of hydrocyanic acid without injuring himself. Mr. Wakley thereupon inquired at Bow-street what the consequences would be if, on his administering a dose of this poison to M. Chaubert, the latter gentleman happened to die. The responsibility was placed on Mr. Wakley's shoulders, but that did not alter his determination to demonstrate to a very large audience the nature of the "experiments." A few weeks after the exposure M. Chaubert challenged the Editor of THE LANCET to a duel with swords or pistols. The Editor replied caustically that "THE LANCET was the only weapon he could fight with in a matter of this kind." The fire king was never again heard of in this country.

BACTERIOLOGY OF ENDOMETRITIS.

IN order to investigate the bacteriology of endometritis, Dr. Brandt of St. Petersburg recently examined twenty-five cases, including hæmorrhagic, catarrhal, gonorrhœal, and septic forms. After carefully cleansing the external genitals, the vagina, and the cervical canal with a solution of corrosive sublimate of the strength of 1 in 1000, with alcohol and with ether, preliminary bacteriological observations on scrapings from the cervical canal invariably giving negative results, the internal surface of the uterus was scraped with a curette, and dry preparations as well as cultures in agar and gelatine were made. The plate method was likewise employed, as were inoculations in animals. The portions of mucous membrane brought away were also carefully examined with the microscope. In almost all cases microbes were found, both pathogenic and non pathogenic—the former, however, preponderating. Of these both cluster and chain cocci were met with, amongst the non-pathogenic bacteria there were occasionally bacilli, but most commonly cocci. It was remarked that cases where pyogenic microbes were found were not clinically distinguishable from others where none could be detected; these pyogenic microbes, however, when injected into animals invariably produced both local and general symptoms, such as abscesses and a rise of temperature. Sometimes, but by no means always, microbes were seen in the substance of the mucous membrane.

ALBUMINOUS PERIOSTITIS.

DR. DZIERZAWSKI communicates to the Polish medical journal, the *Kronika Lekarska*, an article on the so-called "periostitis albuminosa" of Poncet, Terrier, and Lannelongue. He has been able to find, in addition to his own case, twenty-seven cases reported in medical literature. It is an affection of the periosteum characterised by a clear, tenacious exudation, resembling the synovial fluid or the white of egg, and it is of course from this circumstance that the name has been given it. Some authors, as Nicaise, Riedinger, Albert, and Duplay, look upon it as a special pathological form; while others, as Schlange, Roser, Vollert, Garré, and Oliver, are disposed to regard it merely as a variety of purulent periostitis. Dr. Dzierzawski's own view is that it is not a disease *sui generis*, but that it is comparable to those cases of contagious osteomyelitis where a clear fluid exudation is formed owing to a low type of inflammation, or to tubercular cases, where there are infiltrations or cold abscesses. The small number of pus corpuscles can be explained, according to Schlange, by their deficient formation owing to the weakness of the inflammation, or, according to Garré, by supposing a secondary liquefaction of these bodies by the serous exuda-

Digitized by Google

tion. Under some conditions the periosteum may give rise to exudation containing mucus, consequently there is no need to suppose that the pus corpuscles undergo mucous degeneration, and a better name for the affection under consideration would perhaps, according to the author, be "non-purulent osteo-periostitis."

PTOMAINE POISONING.

AN interesting condition, apparently resulting from the ingestion of unwholesome food, is described by Dr. Guttmann in the *Berliner Klinische Wochenschrift*, and a short abstract of the case is given in a recent number of the *Centralblatt für Klinische Medicin*. A man aged thirty, after enjoying part of a somewhat "high" goose, suffered from symptoms of gastric disturbance accompanied by rigors. In five days he was unable to raise his eyes, and he had diplopia and swelling of the parotid and sublingual glands. Twelve days from the commencement nearly all the branches of the right third nerve were affected, as well as the fourth and sixth on the same side. On the left side the condition was similar, but there was no ptosis. The pupils, however, were normal, vision was good, and there was no optic neuritis. There was no paralysis of accommodation. Except for some paræsthesia in the left hand there were no other signs of disease, and in four weeks' time the patient had recovered perfectly. Dr. Guttmann concludes that the case was one of meat poisoning, and he mentions the fact that nuclear palsies, although no cases of complete ophthalmoplegia, have been described as occurring under similar circumstances.

FOREIGN UNIVERSITY INTELLIGENCE.

Geneva.—Dr. Sulzer has been recognised as *privat-docent* in Ophthalmology.

Kharkoff.—Dr. Popoff has been promoted to the Professorship in Ordinary of Anatomy.

Lausanne.—M. Barde has been recognised as *privat-docent* in Hygiene.

Madrid.—Señor Don Rodriguez y Fernandez of Havana has been appointed to the chair of History of Medicine.

Moscow.—Extraordinary Professors Ostrumoff and Mansuroff have been promoted to the chairs of Therapeutics and Dermatology respectively. Dr. Korzakoff has been appointed Extraordinary Professor of Midwifery and Gynæcology.

Warsaw.—Extraordinary Professor Nikolski has been promoted to the chair of Pharmacology.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. C. Hubert de Change, late Inspector-General of the Medical Department of the Belgian Army. He was a particularly skilful surgeon, and while on the surgical staff of the University of Liége he wrote a good deal, and designed several improvements in surgical instruments. During the Franco-Prussian war he was chief of the field lazaret of the First Division of the Belgian Army of Observation, and rendered important services to the wounded who were conveyed across the frontier.—Dr. J. von Hasner, formerly Professor of Ophthalmology in the German University of Prague.—Dr. Smortchevski, senior *chef de clinique* of the St. Petersburg Town Hospital, suddenly, while in the hospital.—Dr. Popoff, Prosector of the Nikolaeff Naval Hospital, St. Petersburg.

IT is believed that Portland will be the place selected for the meeting of the Congress of American Physicians next summer. Cushing's Island will probably be the rendezvous, and the Congress will assemble about Sept. 1st for its annual business.

PRINCESS CHRISTIAN will be present at a public meeting to be held in support of the Royal British Nurses' Association at the Mansion House on Friday, March 18th, at 4 P.M. Sir William Savory, Sir James Crichton Browne, and Sir Dyce Duckworth have promised to address the meeting.

REPORT OF
The Lancet Sanitary Commission
ON
SANITATION IN THE SHOP.

PART II.

THOUGH shop assistants have so much to complain about, but little has been done on their behalf. This is undoubtedly in a great measure their own fault. For reasons which it is not our special mission to investigate or to explain, shop assistants have not resorted to those methods of combination and of association by which the working classes have ventilated their grievances and often obtained redress. The shopkeeper's assistant, though receiving inferior pay and working longer hours, deems himself to be altogether a superior person, and disdains to follow the same tactics as the skilled artisan. Also, as in many shops a commission is paid on the amount of sales effected, this engenders a spirit of competition and antagonism between shop assistants, so that it is difficult to bring them together into one compact and harmonious organisation. Nevertheless, some associations have been formed, and there are the United Shop Assistants' Union in London, the National Union of Shop Assistants, with its headquarters at Manchester, the Scottish Shop Assistants' Union, and the Early Closing Association. These organisations, and the protests raised from time to time in the press, have effected some slight improvements. If this progress is not very effective in itself, it at least suffices to show that there is a possibility of achieving much more. One of the first endeavours, and in this THE LANCET took a leading part, was to provide seats for shop assistants. For young women especially the long hours of standing are most injurious, and we sent circulars round to the principal retail shops of London asking if seats were provided. Many answered favourably, and in consequence of this movement seats were introduced where they had not existed previously. There was even a sort of contrivance invented to meet the case, which consists of a little seat that can be pulled out from under the counter and pushed back again when no longer required. The shop assistants themselves, however, maintain that this reform, though kindly meant, is of but little use to them. The seats in too many cases were provided in deference to a popular outcry rather than from any desire to see the assistants utilise them. The theory of trade is that the assistant should always be busy, and should not have time to sit down. The shopkeeper imagines that if a customer were to enter his establishment and find a number of assistants sitting down behind the counters an impression would be engendered that the shop was not well patronised and did but little business. Therefore, when the shop assistant has nothing to do he has to invent something and pretend to be busy. A shop assistant told us that when he first took a situation he imagined the seats provided behind the counter were meant to be used. He therefore sat down, but his employer soon came up, exclaiming that he wanted someone who was "more lively." Another assistant explained to us that, though there were seats in his shop, anyone found idle was fined sixpence. The assistants therefore had to pretend to work, even when they had nothing to do and there was no work that they could do while sitting. At another very large establishment, which boasts of the seats it provides for its assistants, anyone found sitting down is reprimanded the first time and dismissed on a repetition of the offence. The assistant, who worked there himself, added to this information that there were mirrors on all sides, in which every movement was reflected.

The shop assistants themselves do not, therefore, think that the seats provided behind the counters are of much service. They may be there, but it is not often practical

Digitized by Google

to utilise them. Of course the circumstances differ in various trades, and in restaurants, for instance, there is ample time for sitting down between the rush at the meal hours. In some places, however, the sitting down is not all rest. A vegetarian restaurant was pointed out to us in where, it was stated, the waitresses receive only five shillings a week wages and vegetarian meals! Between the meal hours, when there is nothing to do, the forewoman distributes sewing among the waitresses, and makes them work for her. Probably the owner of the restaurant knows nothing about this, but it is equally hard upon the girls. Nor is this all. During the first month of service they do not receive any wages whatever, as they are then supposed to be only learners. It is not, therefore, always advantageous to work in places where it is possible to sit down during the day. Yet undoubtedly the standing for such long hours is a great and terrible grievance. Young shop assistants have explained to us how towards the evening they became giddy, "a swimming sensation" overcame them, and they continued to serve almost unconsciously. In time they became hardened to this excessive strain, but in the course of years many were obliged to lie up, the most frequent complaint from which they suffered being that of varicose veins.

Terrible as must be the strain of standing fourteen hours a day and sixteen hours on Saturdays, with only about one hour's rest in all for meals, this is greatly intensified at the Christmas season. In the grocery trade especially is the pressure hard to bear, and but few people realise what an amount of acute physical suffering the Christmas pudding causes to the grocer's assistant. At the Christmas season the assistants have often to remain in the shop all night to weigh out parcels of plums, fruit, spice, candied peel, sugar, &c., so as to sell more quickly on the morrow, when the shop will be crowded and overflowing with persons making their Christmas purchases. It would be an act of humanity if customers would get into the habit of buying leisurely some weeks before time their Christmas provisions. Very frequently in the grocery trade the assistants are kept up three nights consecutively. They may snatch a moment or two's sleep. Coffee-bags are, it appears, especially attractive as forming cushions on which a little rest may be obtained, but of course this is contrary to all rules. An assistant described how, during one of these Christmas nights, devoted to weighing and packing, he was so overcome by fatigue that he fell asleep on a marble counter, and only awoke when almost frozen. Workmen thus toiling through the night would be paid overtime, at the rate of perhaps 50 per cent. more than their usual wages. The poor shop assistant gets only a small Christmas-box, varying from half a crown to half a sovereign; but, as one of them put it, "the half sovereigns only come from the princes in the trade."

The long hours which men find so hard to bear are, of course, much more injurious to women. This fact is so obvious that we need not insist upon it. More than three hundred medical men practising in London signed a petition in favour of the Early Closing Bill introduced in the House of Commons by Sir John Lubbock in 1888. The evidence collected by the House of Commons' Select Committee on the Shop Hours Regulation Bill, and published on May 18th, 1886, confirms this view. According to the special report of the Select Committee, drawn up after hearing all the evidence, "the practice of keeping open shops till a late hour of the evening prevails extensively." The Committee state that the prolonged standing and labour, especially in crowded and ill-ventilated shops, "must be exhausting and often injurious to health, especially in the case of girls." The packing of parcels is often done underground, where gas has to be burnt all day. Apprentices and young persons, after working in a workshop the number of hours allowed by the Factory Act, are sent into the retail shop attached to the premises and made to serve customers or to clear up. Thus the spirit, if not the letter, of the Factory Act is disregarded, and another proof given of the fact, on which we insist, that much better protection is given to the artisan and the labourer than to the shop assistants." The Select Committee then added:—

"A widespread desire has also been expressed by grown-up persons employed in shops that in some way their labours also may be limited by law, and your committee believe that employers are not indisposed, as a rule, to such limitation, provided that it takes the form of general early closing of shops ..... Your committee have evidence that in many localities the desire of the great majority of shopkeepers to close early has been frustrated by the dissent of some few individuals, while in many cases the large establishments are induced to keep their doors open longer than they otherwise would do for fear of their customers being diverted to smaller shops in the trade..... It appears, moreover, from the evidence taken before your committee, as well as by that taken before the Factory and Workshop Act Commission of 1876, that a large majority of the inspectors of factories are in favour of some legislative regulation of the hours of labour in shops: Mr. Taylor, inspector in the North-west Lancashire Division, expressed his belief that they are now almost unanimously of this opinion."

The report goes on to say that work in licensed public-houses and refreshment-houses of all kinds "must be at least as fatiguing, and in many respects as injurious, as in shops. ..... In conclusion, your committee, being satisfied that the hours of shop assistants range in many places as high as from eighty-four to eighty-five hours per week, being convinced that such long hours must be generally injurious and often ruinous to health, and that the same amount of business might be compressed into a shorter space of time, recommend this Bill to the favourable consideration of the House."

As a result of this Parliamentary inquiry and of the efforts then made on behalf of shop assistants, the Shop Hours' Regulation Act came into force in 1886. Half a century ago the Factory Act limited the work of women in factories to sixty hours. This Act only limited the work of young persons to seventy-four hours a week. Now Mr. Provand has a Bill before Parliament to extend this limitation from young persons to women; and, again, after the second reading of the Bill, it has been thought necessary to appoint another Select Committee to travel all over the same ground once more. The objection to Mr. Provand's Bill is that it is a direct blow struck against the independence of women, and will make it more difficult for a woman to earn her living than for a man. In some cases, it is thought, women will be discharged, and men employed in their stead. Without entering upon the vexed question of women's rights we may nevertheless urge it as an indisputable physiological fact that, when compelled to stand for long hours, women, especially young women, are exposed to greater injury and greater suffering than men. The proportion of women who are under twenty or only just a little over twenty, and who are employed in shops, is very large. Numerous witnesses testify that healthy looking girls come up from the country; but after a couple of years spent in serving behind the shop counter they become pinched and pale. Not only do they suffer, but their offspring suffer after them. Mr. T. Sutherst, in his book entitled "Death and Disease behind the Counter," quotes the opinion of Dr. B. W. Richardson to the effect that "the diseases incident to these long hours in the young are: anæmia in both sexes; dyspepsia, with much constipation and flatulence; depression of spirits. In the females, the suppressed natural function; and in male and females, the development of pulmonary consumption, where there is a tendency to it. In my opinion, eight hours daily of actual work is the maximum time during which labour ought to be carried on in shops." Mr. Lawson Tait, surgeon of the Midland Hospital for Women, says that, judging from his own experience, "long hours for women produce a great variety of uterine and ovarian diseases, general dyscrasia and anæmia. Women should not work more than ten hours a day, and in many cases not so much as that. A great many cases have come under my observation of women suffering from uterine displacements, chronic inflammatory diseases of the ovaries and tubes." Dr. J. H. Rutherford (Newcastle-on-Tyne) insists more particularly on the general enfeeblement of the mental and moral nature. Dr. Arthur W. Edis, honorary physician to the Dressmakers' Medical Institution, attributes to the long hours and bad sanitation the great prevalence among women shop assistants of "consumption, heart disease, indigestion, dysmenorrhœa, constipation, hæmorrhoids, leucorrhœa, neuralgia, varicose veins, amenorrhœa, and countless other conditions." He also considers eight hours' work sufficient, and argues that the overwork and miseries the girls have to endure drive many to immoral lives. Any amount of evidence of the same description could be adduced, but in quoting the above our object is to show that, though it is most necessary to reduce the hours of work for men and youths, it is still more urgent

Digitized by Google

where women and girls are concerned. Consequently, Mr. Provand's Bill will undoubtedly do good, though it certainly will not put an end to most of the existing grievances. If the only object in view is the preservation of health, there is no reason why its provisions should not apply to adult males; for no one can say it is healthy, even for adult males, to work and stand, often in unhealthy shops, for more than seventy-four hours a week. The shop assistants themselves see no necessity for making any difference between male and female, old or young. Their demand is for a law by which all shops should be licensed to be opened only for a certain number of hours, no matter who are employed therein. Mr. Musset and Mr. Lillington, secretaries of the United Shop Assistants' Union, were particularly anxious that a limit should be put to the number of hours a shop could remain open. In that case we urged that, as the exigencies of trade varied so greatly according to the district and the nature of the occupation, shopkeepers should be free to select their own hours For instance, it would not cause a very great shock or disturbance—and in some cases, that is, with the better-class shops in central districts, would occasion no change at all—if a law was passed rendering it illegal for anyone to keep a shop open for more than twelve hours in the twenty-four. One of the objections to legislation for reduction of hours is that it requires an army of inspectors to enforce such laws. But, in this case, each shopkeeper might be required to take out a licence on which should be inscribed the hours he proposed to keep open. Then, in some prominent place, as is already done with regard to public-houses, an inscription could be put up stating that the shop is licensed to be open for trade from eight in the morning to eight in the evening, or from nine to nine, or any other hour found advantageous by the tradesmen concerned. No additional inspectors would be required. The policeman on his beat could see that each shop closed at the hour indicated over the shop-door. By this also we should get rid of the invidious distinction made in so many projects of law between shop assistants who belong to the shopman's family and strangers. Whether the shop assistant be related to the shopkeeper or not, excessive hours and excessive fatigue are equally injurious; and why should a shop where the assistants belong all to the same family be allowed to compete unfairly with other shops where the assistants are not related?

Something in any case must be done to prevent the physical degeneration of the million or so of men and women who in England work as shop assistants. Abroad the male shop assistants are, in a measure, saved from physical degeneracy by compulsory military service. For so many years at first, and then for so many days each year, they have to join their regiment and go through hard, healthy exercise. But in England the shop assistant has little time for healthy exercise. He cannot join the Volunteers; he has not the time and he is too exhausted. Then, unless in the presence of the enemy, the soldier is never kept under arms for more than four, or at most, in exceptional cases, six hours, and this with intervals of rest; but the shop assistant has to stand at "attention," when he is not actually working, for twelve, fourteen, and sixteen hours a day. In the army care is taken of the health and physique of the soldiers: in the shop these are too often looked upon as negligeable quantities. As a result a few shop assistants have formed the societies to which we have alluded, and we cannot perhaps better conclude this report than by quoting the evidence of Mr. W. Johnson, general secretary of the National Union of Shop Assistants. Mr. Johnson writes to us saying that the inevitable results of shop labour, as at present obtains, is to dwarf the physical and mental capacities of those employed—in short, to produce a state of general debility, to engender nervous complaints, kidney diseases, indigestion, &c, and these maladies prevail more extensively among shop assistants and kindred trades, clerks, &c., than among the general population. Mr. Johnson goes on to say that these, he presumes, arise from "lack of physical exercise, draughty shops, long hours, mental anxiety, insufficient time for eating meals, limbs and mind working at racing speed. The food and bedroom accommodation in some places is vile, outrageous, and abominable. In fact, the nature of the work and its conditions prevent the girls from arriving physically at womanhood. Mentally and physically a large percentage are, in my opinion, unfit for the responsibilities of wifehood, and the same may be said with regard to the men and the effect upon their manhood." Mr. Johnson also suggests that enforced celibacy may be a cause of ill-health. This remark brings us to a last point. There are some large establishments where great care is taken of the assistants. They are provided with many comforts, and even with some luxuries. But they must be single men and single women. They lose their situations if they marry, and in any case the men lose their rights of citizenship, for, as they sleep in dormitories on the premises, they do not come under either the lodger franchise or the householder franchise. Consequently boarding on the premises is not popular with shop assistants. They demand to be free when their work is done, and they urge that hours of work should not be so long and the pay so slight as to debar them from the possibility of living healthy, useful, enjoyable lives.

THE REPORT OF LORD WANTAGE'S COMMITTEE.

No. I.

WE make no apology for returning to a consideration of the Report of Lord Wantage's Committee on the terms and conditions of service in the army. The subject is important—from a national as well as from a medical point of view. It is of interest to the taxpayer and to medical officers of the military services generally. The subject is confessedly a big one, and of extreme difficulty. Disguise it as we may, the fact remains that military service is not popular with "the masses," whatever it may be with "the classes." The Britisher does not like to sacrifice his inherited freedom for the discipline and restraint of army life. Recruits are hardworked in the present day. Drills are not a particularly exhilarating occupation. Young men who enlist are but imperfectly acquainted with the terms proffered them. They look at the promised advantages on a Government poster, and, disregarding all the conditions, find out after enlistment that, what with stoppages and outlay on their clothing, but little is left of their daily pay to spend on themselves. They consequently consider that somehow or other they have been defrauded, and speedily become discontented.

Lord Wantage's committee seem to have fully availed themselves of the opportunity afforded by their instructions. They certainly have not circumscribed their inquiries within any narrow limits. The evidence before the committee has not yet been issued. After referring to the present organisation of the Army, their report discusses the questions of home establishment, recruiting and recruits, the proposals to meet requirements for drafts, deferred reserve pay and pensions, civil employment after leaving the colours, and so forth, here and there touching upon matters of medical and physiological interest. The general report, signed by all the members of the committee, is followed by some remarks from those members who dissent from different portions of it, and notably by an exhaustive contribution, which is really a separate and independent report, from Sir Arthur Haliburton. Sir A. Haliburton is in agreement with the committee on some subjects. His two strong points of objection, however, appear to be these—the admirable nature of Lord Cardwell's original scheme, and the futility and costliness of some of the committee's proposals Whether he is right or wrong in his views, we feel bound to say he has stated them with conspicuous force and ability. We are nevertheless inclined to doubt if his views would be quite the same were he a soldier and as practically well acquainted with the state of the army as he unquestionably is theoretically. The committee is strongly in favour of a "short" as opposed to a "long" service system. There is no other system practicable for creating and maintaining a reserve. The evidence as to the value of the territorial connexion is held to be overwhelming. The committee have no hesitation in stating their belief that the double-battalion system is not only the most economical, but also the best machinery which can at present be devised for furnishing the foreign drafts and effecting reliefs. The fact that England has at one and the same time to maintain an army in India (which may be considered as permanently on active service), adequate garrisons in her colonies, and an army at home,

Digitized by Google

which has to fulfil the dual purpose of home service (including the provision of a force for small wars) and also of feeding the army abroad, lies at the root of the difficulty with which we have to contend. It is in this and in the absence of conscription that we differ from every other military power in Europe. The conditions of the system adopted in 1872, which is the foundation of the present organisation of the army, have never been fulfilled, and the unfulfilled conditions have been precisely those essential to the successful working of the system. Some of the causes of undue strain on the home battalions have been of an exceptional and merely temporary character; but others have not. To mention one among many causes, and disregarding the requirements of small wars, the machinery has been quite put out of gear by the fact that there are eleven more battalions abroad than at home. That is a state of things which was evidently not calculated to last or to be successful. These are, however, matters of military organisation and administration of general interest no doubt, but they do not concern us. All are agreed as to the weak and depleted state of the home battalions. But it must never be forgotten that for war purposes these home battalions always have the reserve to fall back upon. We confess that we cannot see any reason why the Guards should not take a tour of duty abroad.

The great fault found with the present recruit is his youth and the inferior physique due to youth. Given time, he will develop into a satisfactory type of man. As regards the youth of the men enlisted, we must say that so long as we can remember this has always been a subject of complaint, but, conjoined as it is now with a short-service system, its importance is not to be underrated. The committee have no hesitation in saying that the enlistment of any large number of men below the present low physical standard is to be deprecated. Certainly the present standard touches, if it does not already go beyond, the border line of the physical efficiency of the people. It is true that the finger of a small man lends as much impetus to a rifle bullet as the finger of a big one, but that is far from being all that is required in warfare. It is not so much height as weight and build that are desirable in a youth of seventeen or eighteen. A short man of good weight, with fair chest expansion, is more likely to develop into a strong man than a taller youth without corresponding proportions in this respect. The committee appear to think that by improving the pay and position of the soldier not only a larger number, but more mature and stronger men would be attracted to the service. The cost of carrying out their proposals would be great, and the question at once arises whether any reasonble increase of pay would, after all, remedy the evil as far as the youthfulness of the present recruit is concerned. There is no possibility of going back once the soldier's wages have been increased. We confess that we agree with Sir A. Haliburton in doubting whether the number of older men coming forward as recruits would be increased commensurately with the outlay. But, for all that, we consider that the soldier is insufficiently paid, and a number of things suggested by the committee ought, in our opinion, to be done. We imagine that under any circumstances we shall have to regard the army for the first year or two of a recruit's life in it as a nursery, and during that time the young soldier must be fed, clothed, and trained. He is but a youth on enlistment, and unfit for man's work. Added to his immaturity, he is frequently underfed, for the pinch of poverty and the want of work are probably the spurs which drive the larger number of lads into the recruiting-room. As almost any number of lads can be had, while grown men are scarcer, it seems to us that the subject of instituting nursery or probationary battalions might be worthy of consideration. Would it not be possible in this connexion to devise some method of tapping our State-endowed schools or of imparting a military character to the physical education of boys at such institutions? That our recruits are capable of developing into fine men and good soldiers cannot be doubted by anyone who has seen our troops in India and abroad. It is generally admitted that they will compare favourably with any in the world. We agree with the committee in favour of a more elastic system by which soldiers can be allowed to extend their services with the colours, and do not believe that, within limits, it would have any really injurious effect upon the reserves. A bird in the hand is, after all, worth two in the reserve bush. It was a very different thing under the long service system—where recruits, quite as young as they are now, were added to a corps mostly composed of soldiers of many years' service—from what it is now, when corps are composed of soldiers of short service only. On grounds of physical efficiency, discipline, and what may be termed moral grounds, a regiment requires to be "stiffened" with a fair proportion of older soldiers, to say nothing of the maintenance of the non-commissioned ranks. As regards any long extension generally of the soldier's service in India, however, it cannot be said to be advisable on medical grounds. The late Dr. Bryden, while he fully recognised the increased susceptibility of the young soldier to certain diseases in India, held nevertheless that the health statistics of the army under the short service system compared very favourably with those under the long service system in that country.

There are a great many subjects that still remain to be considered, but here we must stop for the present. We are afraid that with a general election in front of us the present Government, at any rate, is not likely to grapple with big and expensive military questions.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Exeter City.—Dr. J. Woodman reports that during the past year 222 patients were under treatment in the city sanatorium, 185 coming from the city itself and 37 from other parts of the county of Devon. The cases were 182 of scarlet fever, 32 of enteric fever, and 8 of measles. During the period 1882-91, there have been 895 cases under treatment in this institution, and of these 44 have died, the percentage of deaths being 4·9. During 1891 the fatality rate was only 1·3 per cent. The hospital is increasingly used, and it speaks volumes to find that, although the number of patients received during 1891 was 108 more than in any previous year, all the cases have come in voluntarily, no legal compulsion having been resorted to. The general death-rate for Exeter was 23·0 per 1000 living, the increase having been brought about by a severe epidemic of measles during the last quarter of the year.

Herefordshire Combined Districts.—Diphtheria has in a number of instances prevailed in this combined area; it has, as is commonly the case, been associated with undefined forms of sore-throat; and its causation has in certain instances been a matter of much doubt and uncertainty. Its prevalence has, at the same time, added force to Mr. V. Sandford's repeated plea for more means for isolating first cases of infectious diseases. The reports refer but rarely to anything but prevalences of such diseases, to death- and birth-rates, and the like; but the inspector of nuisances in some measure supplies the deficiency. Well-cleansing is a not uncommon practice, and yet from the condition of the soil, as described around wells in the Hereford rural district, we should have thought that it was a most untrustworthy method, since it leaves the soil through which the water flows still contaminated and further to be fouled—as, for example, by cesspool soakage At Kingsland Mr. Sandford strongly urges the provision of adequate means of sewerage, and similar provision has been decided on as regards Weobley.

Wakefield Rural District.—After needed correction, the death-rate for this rural district during 1891 is given as 19 per 1000. The zymotic rate is low, but the infant mortality is unnecessarily high. Nine patients were admitted into the isolation hospital, and its use is highly spoken of. The notification system brought 113 cases of infectious diseases to light, and many were dealt with for preventive purposes. The lead poisoning due to potable water is causing anxiety in this as in many Yorkshire districts, and it is to be hoped that before long some satisfactory explanation of the occurrence will be forthcoming. Mr. J. W. Walker appends a quinquennial report which deals with the district statistically, and indicates the improvements effected during the term of years in question.

Barnstaple Rural District.—According to Mr. Joseph Harper the general death-rate for this district during the past year was 15 2 per 1000 on a population somewhat ex-

Digitized by Google

ceeding 19,000. The zymotic rate was 1·4 per 1000, the diseases causing the largest number of deaths being whooping-cough, with 8 deaths, and diphtheria, with 5 deaths. The diphtheria, which was associated with some cases of sore-throat, led to delay in opening the elementary schools after the holidays. Three deaths also resulted from membranous croup, a disease which can rarely be dissociated from diphtheria when any prevalence of that disease exists. One of these "croup" deaths occurred under conditions which appeared to point to one of the forms of paralysis so typical of true diphtheria. Only three fatal cases of scarlet fever took place, but no less than 250 cases were notified. The system of notification is likely to supply information as to the varying fatality of diseases of this class, and so to lead to our learning something as to the conditions which control these variations. Hitherto we have only known that some outbreaks, of scarlet fever for example, occasioned an exceptional mortality, and that others of the same disease, like this prevalence in the Barnstaple rural district, were characterised by a singular absence of fatality; but the reason for the difference has remained largely, if not altogether, unexplained.

Stroud Urban District.—Mr. T. Partridge, in referring to influenza, gives some information as to the prevalence of a kindred disease amongst horses at the same time as the human affection. Diphtheria and scarlet fever also prevailed; but it was difficult to understand either their extent or the relationship of one to the other, owing to the short-sighted action of the authority, who have not adopted the Notification Act, lest it should "injure the trade of the town." Under these circumstances it now goes forth to the public that scarlet fever invaded the town "in an epidemic form," and that had there been notification with isolation these would have helped "materially to stamp out" the disease. How the action of the authority can be good, either for trade or anything else, we fail to see; especially as the death-rate for the town was 19·2 per 1000, or the highest for some years past. The zymotic rate, which was excessive—namely, 3·5 per 1000—led mainly to the increase.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5668 births and 4013 deaths were registered during the week ending March 5th. The annual rate of mortality in these towns, which had been 21·1 and 23·4 per 1000 in the preceding two weeks, declined again last week to 20·5. In London the rate was 18·9 per 1000, while it averaged 21·7 in the thirty-two provincial towns. The lowest rates in these towns last week were 15·3 in Portsmouth, 15·5 in Newcastle-upon-Tyne, 15·7 in Croydon, and 15·8 in Plymouth; the highest rates were 27·8 in Liverpool, 28·8 in Swansea, 30·5 in Burnley, and 32·5 in Preston. The 4013 deaths included 390 which were referred to the principal zymotic diseases, against 388 and 426 in the preceding two weeks; of these, 158 resulted from whooping-cough, 105 from measles, 45 from diarrhœa, 41 from diphtheria, 28 from scarlet fever, 13 from "fever" (principally enteric), and not one from small-pox. No death from any of these zymotic diseases was registered in Brighton; in the other towns they caused the lowest death-rates in Norwich, Bradford, Hull, and Plymouth, and the highest rates in Birkenhead, Swansea, Wolverhampton, and Derby. The greatest mortality from measles occurred in Sunderland, Liverpool, Halifax, and Birkenhead; from scarlet fever in Preston; from whooping-cough in Portsmouth, Burnley, Cardiff, Croydon, Derby, and Wolverhampton; and from diarrhœa in Nottingham and Blackburn. The mortality from "fever" showed no marked excess in any of the thirty-three large towns. The 41 deaths from diphtheria included 27 in London, 2 in Liverpool, 2 in Derby, and 2 in Newcastle-upon-Tyne. No fatal case of small-pox was recorded in any of the thirty-three large towns; 11 small-pox patients were under treatment in the Metropolitan Asylum Hospitals, and 1 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of last week was 1170, against numbers declining from 1397 to 1198 at the end of the preceding six weeks; 96 new cases were admitted during the week, against 82 and 86 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 450 and 460 in the previous two weeks, declined again last week to 379, and were 126 below the average. The causes of 81, or 2·0 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Salford, Oldham, Newcastle-upon-Tyne, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Blackburn, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·1 and 22·8 per 1000 in the preceding two weeks, declined again to 22·5 during the week ending March 5th, but was 2·5 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·5 in Perth and 17·3 in Edinburgh to 24·9 in Glasgow and 26·0 in Paisley. The 626 deaths in these towns included 19 which were referred to whooping-cough, 12 to diphtheria, 11 to measles, 8 to "fever," 7 to diarrhœa, 4 to scarlet fever, and not one to small-pox. In all, 61 deaths resulted from these principal zymotic diseases, against 62 and 68 in the preceding two weeks. These 61 deaths were equal to an annual rate of 2·2 per 1000, which was slightly above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 15 and 24 in the preceding two weeks, declined again to 19 last week, of which 7 occurred in Glasgow, 5 in Aberdeen, and 5 in Paisley. The deaths from diphtheria, which had increased from 1 to 9 in the previous three weeks, further rose to 12 last week, and included 6 in Glasgow and 3 in Aberdeen. The 11 fatal cases of measles showed a decline of 5 from the number in the preceding week, and included 10 in Glasgow. The 8 deaths referred to different forms of "fever" exceeded by 3 the number in the previous week, of which 6 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had increased in the preceding three weeks from 146 to 165, declined last week to 155, but slightly exceeded the number in the corresponding week of last year. The causes of 67, or nearly 11 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had risen from 31·8 to 39·5 per 1000 in the preceding three weeks, declined again to 32·7 during the week ending March 5th. During the first nine weeks of the current quarter the death-rate in the city averaged 38·8 per 1000, against 30·8 in London and 19·8 in Edinburgh. The 219 deaths in Dublin during the week under notice showed a decline of 46 from the high number in the preceding week, and included 8 which were referred to whooping-cough, 7 to measles, 4 to "fever," 2 to diarrhœa, and not one either to small-pox, scarlet fever, or diphtheria. In all, 21 deaths resulted from these principal zymotic diseases, equal to an annual rate of 3·1 per 1000, the zymotic rate for the same period being 2·2 in London and 1·0 in Edinburgh. The fatal cases of whooping-cough, which had been 3 and 8 in the preceding two weeks, were again 8 last week. The deaths referred to measles, which had been 3 in each of the previous two weeks, rose to 7 last week, a higher number than in any week since January, 1890. The 4 fatal cases of "fever" showed a decline of 3 from the number in the preceding week. The 219 deaths in Dublin last week included 30 of infants under one year of age, and 62 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from the numbers recorded in the preceding week. Seven inquest cases and 5 deaths from violence were registered; and 65, or nearly a third, of the deaths occurred in public institutions. The causes of 23, or more than 10 per cent., of the deaths in the city last week were not certified.

NEWARK HOSPITAL AND DISPENSARY.—The report for the past year of the resident medical officer showed that 1439 cases had been treated during the year—namely, in-patients 164, out-patients 983, casualties 145, and dental cases 147.

THE SERVICES.

THERE are thirteen votes in the Army Estimates among the effective services. The first, which is the largest item of all, is for pay of the Army. This amounts to £5,635,000, against £5,632,700, an increase of £2300. The vote for medical establishments amounts to £290,100, a decrease of £2700 on the current year—£292,800.

THE ROYAL WARRANT FOR THE INDIAN MEDICAL SERVICE.

The Royal Warrant for the above service published in the Indian journals is the outcome and consequence of what has been done in this country for the Medical Staff. It cancels former warrants, and lays down the substantive ranks and military titles of the medical officers of the Indian military forces on the lines adopted in the case of the Medical Staff, and it revises the rules for the promotion and precedence of the Indian Medical Service in accordance with the latest ruling on the subject, with such modifications and adaptations as are necessary for the purpose.

Surgeon-General Geo. Smith, M.D., late Indian Medical Department, Madras Presidency, died on the 23rd ult.

Dr. George J. Shaw, Deputy-Inspector-General, Bombay Army, and late Assay Master, Madras Mint, died at Ventnor on the 3rd inst., aged seventy-three.

Surgeon-Captain J. D. Moir, Army Medical Staff, has been appointed to the Brigade of Foot Guards in London.

The following Surgeon-Captains of the Medical Staff have now completed twelve years' service, and become entitled to promotion to the rank of Surgeon-Major:—F. R. Barker, M.B.; A. Keogh, M.D.; C. B. Hill; J. R. A. Clark, F.R.C.S. Edin.; H. J. Michael; T. Dorman, M.D.; A. W. P. Inman, M.B.; T. M. Corker, M.D.; E. H. Myles, M.B.; T. B. Moffitt; C. A. Webb; H. Martin, M.B.; A. F. J. Croly, F.R.C.S.I.; R. O. Cusack; E. F. Smith; W. D. A. Cowen; R. H. Forman, M.B.; S. J. Flood, F.R.C.S. Edin.; G. W. Robinson; J. Watson, M.D.; O. Todd, M.B.; A. O. Geoghegan, M.D.; J. D. Day, M.B., F.F.P.S. Glasg.; A. M. Kavanagh; J. G. Harwood, F.R.C.S. Edin.; R. D. Donaldson, M.D.; H. L. E. White; A. H. Burlton; E. North, F.R.C.S. Edin.; G. F. Poynder; G. F. A. Smythe, F.R.C.S. Edin.; H. L. Battersby; A. Hewett, F.R.C.S. Edin.; P. Mulvany; J. E. Nicholson; W. O. Wolseley; T. F. MacNeece; B. T. M'Creery, M.B., F.R.C.S.I.; A. P. O'Connor, F.R.C.S.I.; J. M'M. Bolster, F.R.C.S.I.; D. Wardrop, M.B.; G. T. Goggin; J. M. Jones; F. M. Baker, M.B.; A. Asbury, F.R.C.S.I.; P. M. Carleton, M.D.; F. B. Maclean; R. W. Barnes; and P. H. Fox, F.R.C.S.I.

ARMY MEDICAL STAFF.—Surgeon-Captains T. R. Lucas and J. C. Connor have been posted to the Rangoon District, Madras command, for duty. Surgeon-Captain D. D. Shanahan has been transferred from the Madras District to the Rangoon District; the duties of Principal Medical Officer of the Woolwich District are performed by Surgeon-Lieutenant-Colonel M. M. Gallwey until Surgeon-Colonel P. Broke Smith joins for duty.

ARMY MEDICAL RESERVE OF OFFICERS. — Surgeon-Captain Richard T. Cæsar to be Surgeon-Major (dated March 9th, 1892).

NAVAL MEDICAL SERVICE. — The following appointments have been made at the Admiralty:—Fleet Surgeons: John K. Conway, M.D., to the *Liffey;* George Curtis to the *Victory*, additional; Richard J. Sweetman to the *Dædalus;* and Robt. H. More, M.D., to the Plymouth Division Royal Marines (all dated March 5th, 1892); Thomas C. Hickey to Haslar Hospital (dated March 8th, 1892). Staff Surgeons: Richard D. White, M.A., M.D., to the *Boadicea*, and Jas. A. Collot to the *Collingwood* (both dated March 5th, 1892); William A. Breton, M.D., to the *Superb* (dated March 19th, 1892); and Robert M'Iver to the *St. Vincent* (dated March 8th, 1892). Surgeons: Robert Hill to the *Surprise* (dated March 8th, 1892); Alfred T. Rimell to the *Alexandra* (dated March 24th, 1892); and John Ottley to the *Victory* (dated March 13th, 1892). Surgeons and Agents: James H. Bogan at Arthurstown, and William J. Shee at Fethard (dated March 4th, 1892).

VOLUNTEER CORPS. — *Rifle:* 2nd Volunteer Battalion, the Welsh Regiment: Surgeon-Captain J. H. Davies to be Surgeon-Major (dated March 5th, 1892).—3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): James Mason, Gent, to be Surgeon-Lieutenant (dated March 5th, 1892).

Correspondence.

"THE LARYNGOSCOPE IN ENGLAND."

To the Editors of THE LANCET.

SIRS,—In your annotation on the first use of the laryngoscope in England you have forgotten to mention the name of Dr. Walker of Peterborough. He is the author of "Larynx" in Quain's Dictionary, and was amongst the first, I believe, to bring the instrument into practical use. I well remember seeing Czermak at the London Exhibition, and how he displayed his larynx to the multitude as he ran up and down the musical scale, declaring that providence had given him a special mouth and throat for the demonstration. It was at this period that the laryngoscope came into practical use; but as you allude to previous inventors of the instrument, I may remind you that you have omitted to mention the name of our countryman, Dr. Benjamin Babington. In the *Medical Gazette* the following may be found referring to a meeting of the Hunterian Society in March, 1829: "Dr. Babington submitted to the Society an ingenious instrument for the examination of parts within the fauces, not admitting of inspection by unaided sight. It consisted of an oblong piece of looking-glass set in silver wire, with a long shank. The reflecting portion is placed against the palate, whilst the tongue is held down by a spatula, when the epiglottis and upper part of the larynx become visible in the glass. A strong light is required, and the instrument should be dipped in water so as to have a film of fluid upon it when used, or the halitus of the breath renders it cloudy. The doctor proposed to call it "glottiscope." Dr. Hodgkin refers to the instrument in his lectures as "the speculum laryngis, or laryngoscope invented by my friend Dr. Babington in 1829.'

I am, Sirs, yours faithfully,

Grosvenor-street, March 5th, 1892. SAMUEL WILKS.

ROYAL COLLEGE OF SURGEONS, IRELAND.

To the Editors of THE LANCET.

SIRS,—As the election of a President and Vice-President of the Royal College of Surgeons in Ireland must be held annually (June) according to the present Charter, it is most desirable that the Council of the College should bestir themselves to obtain the necessary alterations to enable a President and Vice-President to be elected biennially only, and thus prevent unseemly contests, as occurred in the time of the President just preceding, and which must from time to time again occur; this would be the only correct settlement of a question of biennial presidency, which does not now and cannot exist until the necessary alteration of the Charter is made. At present there must be not only a yearly election for the President, but a re-election should the outgoing President seek to be re-elected, and who may or may not be opposed. True, many have held the office of President for two, three, and four years, such as Crampton, Cusack, and others. Croker-King was the first who held the office for two years consecutively, but he had to be re-elected, and the present President was elected without opposition for a second term. Some of the younger and less experienced members of the corporation of the Irish College have erroneously formed the opinion that being re-elected to the office of President for a second year signifies a "biennial presidency." But, as required by Charter, a new election has to be held at the expiration of each year. I cannot but agree with those senior men of the College that not any such office as biennial presidency exists, and could not, as it would be contrary to the words of the Charter—viz., "The Fellows shall elect *yearly* by ballot out of their own body one person President and one other person to be Vice-President, and which persons shall serve during one whole year." It would just be as rational to call the present Lord Mayor of Dublin a biennial Lord Mayor because he has been re-elected to the mayoralty for two years consecutively. I have written at length with the endeavour to persuade Fellows of the College that a biennial presidency of the College of Surgeons does not exist, and cannot until the Charter is altered, and express a hope that the necessary

Digitized by Google

alteration may be obtained; for, as at present, there is nothing to prevent a contest either at the first or second candidature, which occurred to the present President, not only at his first candidature for the presidency, but also upon another occasion, and to the preceding President upon his second candidature, and not unlikely to occur when the Vice-President seeks promotion to the presidential chair.

I am, Sirs, yours truly,

Dublin, March 7th, 1892. F.R.C.S.I.

POST-MORTEM APPEARANCES OF THE BRAIN OF INFLUENZA PATIENTS.

To the Editors of THE LANCET.

SIRS,—When dealing with the subject a fortnight since I confined myself to a bare record of facts which appeared worthy of consideration by the side of certain statements made by a Danish observer upon the same topic, and brought forward by Dr. Althaus in his letter of the 13th ult. I propose now, with your permission, to deal chiefly with matters of opinion. In my opinion the statements bearing upon this subject, which are quoted by Dr. Althaus in his letter of the 5th inst., invite criticism. I am not at all prepared to concede that the "series of records" therein referred to is "very significant." I am disposed to believe that much of the apparent significance will disappear upon examination. In the first place, we are promised information concerning twelve necropsies of influenza cases; three of these have no bearing upon the subject in question, for in them the condition of the brain is not mentioned. Nine cases remain. Now I think that exception may fairly be taken to Nos. 2, 3, 9, and 10 (adopting the figures given); it is doubtful whether the appearances described in these had any real association with influenza. In No. 2 there was "copious hæmorrhage at the base of the brain, proceeding from an aneurysm of the basilar artery"; further, blood in a lateral ventricle, and "granular ependymitis." I am unable to see the bearing of this upon the pathology of influenza. Are we to gather that a hyperæmic state of the basal blood-vessels—such as is supposed to be present in influenza—by causing additional strain led to the rupture of the aneurysm? I am disposed to think that any stress which may have been put upon the diseased artery is more likely to have been due to a fit of sneezing or coughing than to any such theoretical cause as that suggested. As regards granular ependymitis, that condition is too commonly seen to have any significance in the present case. In Case 3 "the dura was completely adherent to the skull, and the pia thickened and strongly congested." There is no evidence here of recent disease—nothing whatever to exclude the supposition that the appearances were independent of and antecedent to the attack of influenza. The adhesions may have been strong, difficult to break down (i.e., old), the pia opaque and tough, as well as thickened, and the patient an old alcoholic. Case 9 showed "general subarachnoid œdema" only. There is no mention of the state of the lepto-meninges, and certainly no reason for inferring that the œdema was associated with undue vascularity of these membranes, owning a special cause. The age of the patients is not stated. Perhaps the brain was in a measure atrophied, in which case the œdema was probably compensatory and any vascular congestion present merely arose *ex vacuo*. In Case 10 we have to deal with "a tubercular and alcoholised person." The post-mortem appearances were those found in tubercular meningitis; even the "strong subarachnoid œdema" may, I think, be reasonably referred to this affection; if not, alcoholism has in any case to be reckoned with, which is quite capable of producing such œdema in association with cerebral atrophy. I am, in short, unable precisely to understand the claim of this case to figure in its present position. Five cases remain for consideration—Nos. 1, 4, 8, 11, and 12. Case 1 showed "great hyperæmia in the right hemisphere of the cerebellum, with hæmorrhagic spots and complete softening of the medullary matter." No other morbid appearances are stated to have been present. Surely this is a curiously limited mode of pathological expression, granting that the cranial contents are in some way implicated in influenza. We might at least expect hyperæmia elsewhere—at the base of the brain, for instance. Might not the same accidents as those referred to as capable of causing rupture of an aneurysm bring about rupture of diseased vessels in the cerebellar hemisphere? The hæmorrhagic spots and the softening (a secondary process) would thus be accounted for. In Case 11 there was "slight subarachnoid œdema and lepto-meningitis with hyperæmia." It is not stated that the inflammation was acute and recent, and the omission necessarily detracts from the interest of the case. Cases 4 and 12 showed different degrees of lepto meningitis (acute); Case 8, "hæmorrhagic pachymeningitis, chiefly in the middle fossæ." Again, I would remark that we are not told whether the inflammation in this last case was recent or not. The affection spoken of may be met with, even outside asylums, in a chronic form. As regards the habits and history of the case we know nothing.

In my opinion, any significance which may attach to these cases (as a whole) is concentrated in Nos. 4 and 12, and I believe that even the morbid appearances in them can be reasonably explained in more ways than one. Some might be disposed to associate the inflammation described with the action of a microbe special to influenza. For my part, I consider that these two cases of acute lepto-meningitis may not unfairly be ascribed to pre-existing pneumonia. Doubtless meningitis is a very rare complication of pneumonia; but lepto-meningitis in influenza is probably equally rare. It may be further objected that the pneumonia occurring in influenza is merely secondary, not the specific disease which occasionally precedes meningitis. To this I would reply that Fraenkel's diplococcus (found alike in lobar pneumonia and meningitis) occurs in secondary as well as in primary pneumonia; and further, that other inflammation-generating organisms which might well cause meningitis occur in the lung of secondary pneumonia—for example, streptococcus pyogenes and staphylococcus aureus. With apologies for trespassing upon your space to such an extent,

I am, Sirs, yours faithfully,

EDWIN GOODALL, M.D. Lond.

West Riding Asylum, Wakefield, March 8th, 1892.

To the Editors of THE LANCET.

SIRS,—Having read Dr. Goodall's account in a recent number of THE LANCET, purporting to be a verified record of the pathological appearances as observed in the brain of patients dying of influenza, the following facts may be of some little interest as supporting the views set forth by Dr. Althaus. In one instance only have we had the opportunity of examining the brain of a patient dying from influenza. In this case the pia mater was thickened and excessively congested, there was an excess of subarachnoid fluid, and a more or less general cortical hyperæmia. But the most remarkable pathological appearance was the intense congestion, almost amounting to capillary hæmorrhage, of the medulla. This condition of the bulb Dr. Goodall does not seem to have met with, which is all the more remarkable when the apparently trustworthy records published by Dr. Althaus are read in conjunction with the facts here stated. The case forming the subject of these notes died from broncho-pneumonia after an illness of five days. In addition to a high temperature and general prostration, the most noteworthy clinical fact was persistent vomiting. There would seem to be some justification for drawing a relationship between this symptom and the congestion of the medulla.—I am, Sirs, yours faithfully,

P. W. MACDONALD, M.D.

Dorset County Asylum, March 8th, 1892.

"THE EFFECTS OF INFLUENZA UPON THE MIDDLE EAR."

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to Sir Wm. Dalby's paper under the above heading, published in THE LANCET of Feb. 20th, by Dr. Walker Downie's letter in your last issue. I quite agree with the latter's remarks, and would take most emphatic exception to Sir William Dalby's statement "that those with healthy ears have little to dread from influenza." My experience both in private and hospital practice of the three epidemics of 1890, 1891, and 1892, most decidedly does not agree with it. I have had a large number of cases under my care of acute middle-ear suppuration and of non-suppurative catarrh, the effects of influenza. In the suppurative cases the inflammatory action was exceptionally virulent and rapid. On the authority of the

Digitized by Google

patients, among whom were several medical practitioners, they most of them had healthy ears before the attack, and I myself suffered from an acute and exceedingly painful attack of the non-suppurative variety during the 1890 epidemic.

I am, Sirs, yours faithfully,

W. R. H. STEWART,

Aural Surgeon to the Great Northern Central Hospital, &c.

Devonshire-street, Portland-place, March 7th, 1892.

PUBLIC EXECUTIONS.

To the Editors of THE LANCET.

SIRS,—I observe in the *Standard* for March 7th the following passage:—"In consequence of the recent order, authorising the medical officers of Her Majesty's prisons to decide the length of drop required for a condemned prisoner, Berry, the public executioner, has resigned his position." If it is true that the executioner has resigned in consequence of interference with his unpleasant duty by a prison doctor, I for one am not at all surprised at it, for it is not the duty of a prison doctor to do more than certify that the death sentence has been carried out, and any meddling with the mechanical details of an execution is not only unworthy of the position of a medical man, but must necessarily make the prison doctor responsible for a properly carried out execution. I am a prison doctor, but I have not seen the order which is above alluded to, and my disposition would be to decline to act as hangman's assistant, either to Berry or any other person appointed for the purpose by a sheriff. It has always seemed to me a matter for regret that a prison doctor should have made a study of the science of hanging, and thereby brought upon prison doctors responsibilities which do not belong to them. I can fancy the heckling that prison doctors will henceforth receive from coroners' juries. Berry generally was out of reach when the inquest was going on, but a prison doctor cannot get away so easily, and if in the future any untoward accident happens at an execution the prison doctor will probably be held up to public ridicule. I am not without experience of executions, and look forward to deaths on the scaffold with feelings akin to horror; but what will be the sensations of a prison doctor when watching for the drop when the length of rope given has been his own calculation. I hope other prison surgeons have thought over the matter if the paragraph quoted has been observed by them.

I am, Sirs, yours faithfully,

"FIAT EXPERIMENTUM IN CORPORE VILI."

March 9th, 1892.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Street Noises and their Prevention.

WITH reference to the annotation on the above in THE LANCET of last week reference may be again made to a very wholesome local Act which certainly shows one advantage of local government. Some years ago street music was an intolerable nuisance here, and no streets were more infested than those inhabited by medical practitioners. The local Act contains the very reasonable proviso that any householder may personally, or through a relative, servant, or police constable, request a street musician to go away *out of his hearing*. If, after receiving such a request, the musician continues to play, he or she is liable to a fine of forty shillings. A little firm persistence in enforcing this very wholesome regulation has worked wonders, converting a well-known "doctor's street" from the pandemonium it used to be to a quiet neighbourhood. Another nuisance which has been dealt with by local Act was that caused by screeching cart wheels. It was wholly avoidable, as was proved by its discontinuance when it came to be punishable by fine. Street cries still continue, but to a less extent than formerly.

Suicides and Crimes of Violence.

These have been rather frequent of late, which is somewhat unusual, spring and autumn being the seasons in which these lamentable occurrences generally occur in more or less epidemic form. A mother has been committed for trial for the alleged murder of her two young children by strangulation. An adjourned inquest is to be held by the city coroner on Saturday on the body of a citizen, who first shot a young woman with a pistol, terminating his own existence with another shot from the same weapon. The young woman still remains in the Northern Hospital in a very serious state, and it is very unlikely that she will be able to attend the adjourned inquest, as had been hoped.

Kirkdale Gaol.

The building which for many years received prisoners from this city and from the county has been finally closed, this having been gradually effected during the last few months. Kirkdale Gaol, as it was called even after it became Her Majesty's prison, was first occupied in 1819 as a house of correction. It was then in a very isolated position, situated three miles north of the centre of Liverpool, and in what must have been a pleasant situation until spoilt by brick-kilns. Without and within its walls have been executed all the criminals condemned to death at the Liverpool Assizes since their being first held in Liverpool in 1835, with the one exception of Elizabeth Berry, executed within the precincts of Her Majesty's prison at Walton some years ago for the murder by poison of her daughter. All future executions will take place in this same prison in a place specially erected for the melancholy purpose.

Death from Alleged Irritant Poisoning caused by Eating Tinned Salmon.

An inquest was held by the deputy county coroner this day on the body of a girl aged thirteen, who died on Monday at the house of her employer. On Friday, the 4th inst., the deceased partook, with two other persons, at tea, of a tin of salmon. This was at half-past six, and deceased went back to her place. Her mistress, who had seen her before she went out in her usual good health and spirits, noticed that on her return she looked cold and ill. She complained of stomach-ache, and after having some warm tea she went to bed. Next day (Saturday) and all Sunday she was ill, complaining of stomach-ache and vomiting. At half-past nine on Sunday night she moaned a little, and her mistress gave her some brandy. As the deceased said that she was comfortable, she was left for the night. On Monday morning she came downstairs complaining of great thirst and looking very ill. Even after three cups of tea she felt thirsty. Dr. Mitchell was then called in and pronounced her to be very seriously ill. They laid her on a couch in the kitchen, and she died soon after the doctor's visit. Dr. Jackson, who made the post-mortem examination, deposed that death was caused by acute inflammation of the bowels, and Dr. Mitchell expressed an opinion that the symptoms pointed to poisoning. The deceased's sister, who had also eaten the salmon, felt sick, but recovered, while a seafaring man who also had it felt no ill-effects whatever. The jury found that the cause of death was inflammation of the stomach set up by an irritant poison.

March 9th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Proposed "Gresham" University.

THE new University for London under its changed name finds no more favour in Manchester on the lines of the present proposed charter than it did before. On the broad principle of a Teaching University for London no objection is raised; quite the reverse. The head and front of the offending is to be found in the provisions respecting the granting of medical degrees, and it is alleged by the objectors that, if the present scheme be sanctioned, a great and lasting injury will be done to all provincial medical schools; or, to put it in the words of the report of the Council of Owens College, protest is made "against the establishment of a new university, from whose constitution the necessary safeguards for a maintenance of a high standard of medical education and training are conspicuously absent."

Owens College.

At the half-yearly meeting of the Court of Governors of the College last week several matters of medical interest transpired. The Duke of Devonshire was elected President,

Digitized by Google

to fill the vacancy caused by the decease of his father, the late Duke, who had held the office for more than twenty years. The appointments of Dr. Dreschfeld to the chair of medicine and Dr. Delépine to that of pathology were confirmed. The minimum age of admission of any student to the College was raised from fifteen to sixteen years, though as a matter of fact but few students of late years have been under the latter age. It was reported that arrangements are in progress between the College and one or two of the smaller medical charities for the adaptation of certain houses on the College estate to hospital purposes, where facilities will be given for instruction in the special subjects of skin diseases, cancerous diseases, and diseases of women and children. These arrangements are, however, in a state of suspense, pending the decision of the authorities of the Royal Infirmary with regard to the proposed hospital extension. Another link between the College of the present and the College of the past has been severed by the resignation of Professor Williamson, F.R.S. For forty years he has occupied the chair of Botany. Though in the early days of the College this was combined with Geology and Zoology, these latter have long since had professors of their own, leaving Professor Williamson free to follow his favourite study. As a medical man he is scarcely known, his professional work having for many years been entirely subordinated to his scientific work. A farewell address from the Senate of the College was presented to him in the College library, the principal, Dr. Ward, paying an eloquent tribute to his life-long services to the College in particular and to science at large. Mr. F. E. Weiss, of University College, London, has been appointed his successor. The additions to the buildings of the medical department are now in progress, towards the expense of which upwards of £18,500 has been subscribed; but a considerably larger sum will be required to complete the work, and a further appeal to the public is to be made.

Provident Dispensaries.

The Manchester and Salford Provident Dispensaries Association has just held its annual meeting. A very flourishing and, from a managerial point of view, satisfactory account was given of the year's work. Six out of the nine dispensaries are self-supporting. The subscriptions of members amounted to £4183, and the sums paid to the medical staff reached £2653; but the amount of work done by the latter was not stated, though it is reported that no less than 24,000 persons are entitled to medical attendance by the medical staff. One influential member, Mr. Gustav Behrens, asserted that in his opinion the doctors attached to the dispensaries had not been remunerated to the extent which he thought was their due. On a proposal to make a new rule, "by which any medical man could have his agreement terminated by three months' notice from the Council," a warm discussion arose, one member of the staff writing to say that if such a rule were made he should at once resign and "expose the so-called philanthropy of the Council, who make medical men the scapecoats of their vicarious philanthropy."

Death of Dr. Ross.

Manchester and the profession at large are losers by the untimely death of Dr. James Ross. A Scotchman of robust physical frame, he was attacked something more than a year ago with malignant disease of the stomach, though he bravely kept at his work until within a few weeks of the end. His funeral, on the 1st inst., was attended by a large assembly of medical men, representatives of the leading medical charities, and others.

Medical Men and Local Government.

Amongst the successful candidates at the elections to the Lancashire County Council is Dr. Rhodes of Wilmslow, who was returned by a large majority for the district of Withington. Dr. Rhodes has for years taken an active part in the work of the Chorlton Guardians; it is understood he will now resign his seat upon that Board.

Dr. Braddon, who for many years has practised at Cheetham Hill, has consented to become a candidate for a vacancy recently created in the City Council. His presence there would be a decided acquisition to the Council, which is not too strong in professional men as distinguished from those engaged in purely business pursuits.

Manchester, March 8th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle Hospital for Diseases of the Skin.

THE annual report presented at the meeting of the Hospital for Diseases of the Skin showed that 536 new patients had been under treatment, and that over 2232 separate consultations had been given. The financial state of the hospital was satisfactory, the balance being in its favour. The committee desired most thankfully to acknowledge the increased interest taken in the hospital by numerous bodies of working men, as evidenced by their combined subscriptions, and especially to thank Mrs. E. P. Barnes of Sunderland for her handsome donation of £100.

Hexham and Influenza.

Dr. Jackson, the medical officer for Hexham, reports as to influenza, that although influenza was only credited with one death last year, it had indirectly, he had no doubt, caused many. The late epidemic was more severe and complicated in its character than that of 1889 or 1890. It attacked Hexham with the first appearance of winter weather, when both whooping-cough and measles were prevalent, thus taking its victims at a disadvantage and causing a lamentable mortality. Dr. Jackson says as to the cause of the disease he knew nothing, nor was anything known, although it was not a new disease, having visited this country and the whole civilised world at irregular intervals, with more or less severity, since the year 1100. Dr. Jackson believes it to be infectious, but that with proper care it does not of itself prove fatal.

Frivolous Complaints against a Union Medical Officer.

A medical officer of a district in the Malton Union has "been had up," as the expression is, before the Malton guardians to answer complaints of not visiting a pauper patient for ten days, and not attending in his appointed place at the proper times. The local papers say that the doctor denied the chief allegations made against him, and produced his journal in proof of his *bona fides*, showing that it was impossible for him to be at various places at the same time, and further expressed his readiness to carry out his engagements with the guardians so far as was possible. The guardians accepted his explanations; but meantime a great injustice has been done the medical officer in having his name pilloried, as it were, in the local papers for an unsustained charge of neglect.

South Shields: Low Death rate.

South Shields would seem to be again getting up its reputation as an exceptionally healthy seaport, as the rate for the week ending Feb. 20th was only equal to an annual death-rate of 13·3 per 1000 of the population, while the zymotic death-rate was just 1·2. Since then the rate has not been so very low, but there has been no zymotic death.

Sunderland.

The customary annual collections for the infirmary were made in all the Sunderland churches and chapels on the 20th ult., but most unfortunately, owing to the previous heavy fall of snow, the streets were in a wretched condition, and the collections suffered thereby. A new scheme in connexion with the Sunderland Infirmary has lately been put in operation, which promises well. The workmen's committee and some volunteers have divided the town into districts, and call at the workshops and places of business once a month to take up a systematic collection. About ninety persons are engaged in the work.

Newcastle Health Society.

The fourth of the series of lectures now being delivered under the auspices of the Newcastle Health Society has been given by Dr. V. Rutherford to a large and appreciative audience, on "The Skin." In the course of his lecture Dr. Rutherford referred to the water-supply a few years ago to several large towns, and said that out of ten large cities of the United Kingdom Newcastle stood fourth, with 35 gallons per head per day, Glasgow being first, with 53 gallons; Dundee second, with 40 gallons; and Edinburgh third, with 39 gallons. Of the same ten towns, only three—Birmingham, Bradford, and Newcastle—put a prohibition upon cleanliness by charging extra for baths. Dr. Rutherford said at the same time many householders did not utilise the water-supply and baths which they had,

Digitized by Google

and he mentioned instances which had come under his notice where baths were fitted with shelves &c., and used as receptacles for pots, pans, &c.

Cremation in the North.

Dr. Drummond of South Shields has delivered an interesting lecture on cremation before the Literary and Scientific Society of that town. He, being supported by many of his fellow-practitioners, is a strong advocate of cremation, and adduced all the arguments which are now put forth in its favour. Cremation does not, however, seem to make much headway in the north; at Darlington I believe there is a crematorium, but I have not heard of its being much, if at all, used.

North of England Surgical Aid Society.

The annual meeting of this very useful Society has been held in the city; the Bishop of Newcastle presiding. Dr. Arnison read the report, which was satisfactory so far as the working of the Society was concerned; on the other hand, it showed that the help received from the general public had not increased, but working men had largely increased their support, and they promised still more this year.

Death of Dr. G. Y. Heath of Newcastle.

I regret to say that Dr. Heath (of whose serious illness I apprised you in a previous communication) died at his residence, Cocken Hall, near Durham, on Friday last, the immediate cause of his death being, it is said, hepatic disease and gall-stones. This is not the place to attempt to do justice to the successful and brilliant career of Dr. Heath, whose death will be felt as a blow to the profession all over the northern counties of England, and indeed by his old pupils in many distant lands.

It is stated that, for the benefit of the county of Westmoreland, Messrs. Bindloss of Kendal have handed to the secretary a cheque for £1000 as a donation to the Royal Albert Asylum for Idiots, Lancaster.

Newcastle-upon-Tyne, March 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Presentation of a Portrait of Professor Gairdner to Glasgow University.

To commemorate his great services to medical science and their affectionate regard for their old teacher, Professor Gairdner's former pupils are taking steps to have his portrait presented to the University of Glasgow. Sir George Reid, President of the Royal Scottish Academy, has accepted the commission; and it is intended that each subscriber should receive a reproduction of the painting by photogravure or otherwise. A circular has been issued to all Dr. Gairdner's pupils, whether in Edinburgh or in Glasgow, whose addresses have been found. Any former pupils who have not received a copy may communicate with the honorary secretaries, Dr. Joseph Coats and Dr. George S. Middleton, Glasgow.

Complimentary Dinner to Dr. Haycraft.

Dr. Haycraft is to be entertained to dinner, on the occasion of his leaving the University of Edinburgh, by his professional brethren and friends in the city. This is intended as a recognition of his services in connexion with the Association for the Reform of Medical Education, and as an expression of sympathy with him under present circumstances. The dinner is to be on the 17th inst., and Dr. James is to occupy the chair.

The Edinburgh Medico-Chirurgical Society.

At the meeting of this Society last week Dr. John Macpherson (Larbert) showed a patient who had been affected with myxœdema, and whom he had treated by implanting the thyroid of a sheep under the skin below the mammæ. The patient's symptoms were markedly altered, and her general condition, especially the mental condition, showed a very great improvement. The strange point in the case is that the improvement was decided within twelve hours after the operation; thus suggesting the possibility of some other explanation of the results. Dr. W. Russell showed a number of pathological specimens, including a lung with acute miliary tubercle taken from a man over seventy years of age, who died after a few days' illness, which was ushered in by a rigor, and presented the character of influenza with pulmonary congestion; a lung showing the scar of a bayonet wound, and another lung with a localised patch of necrotic pneumonia. Dr. Dawson Turner showed a universal electrical battery. Dr. R. W. Philip read a long and elaborate paper on "A Thousand Cases of Pulmonary Tuberculosis, with Etiological and Therapeutic Considerations." The cases were classed under occupations and sex, and gave results corresponding in the main with the statistics of others. As regards the question of heredity he had only succeeded in ascertaining the existence of hereditary predisposition in a comparatively small percentage of his cases. He laid much stress upon the infectiveness of tuberculosis, and gave instances illustrating this point; he advocated treating phthisis like other infectious diseases, and preventing phthisical persons being engaged in workrooms and shops with others. He further advocated the establishment of hospitals where they might die in comparative comfort, and their removal to which would lessen the risk of infecting those about them. He only touched on the therapeutic side of the question, reserving that for another occasion. Mr. A. Lockhart Gillespie read "Notes on Toxic Effects of Exalgine."

Health of Edinburgh.

The mortality last week was 82, making the death-rate 16 per 1000. Diseases of the chest accounted for at least 24 deaths, and zymotic diseases for 3. The intimations for the week comprised: typhus fever, 1; typhoid fever, 2; diphtheria, 2; scarlatina, 19; and measles, 80.

Edinburgh Sanitary Protection Association.

The annual meeting of this Association was held on Monday, and was presided over by Sir Douglas Maclagan. The report showed increasing prosperity and usefulness during the past year; and the fact that some of the larger schools in the city had been placed under the engineers of the Association for inspection was referred to with special satisfaction.

Meat Inspection in Edinburgh.

It was mentioned lately that a sub-committee of the Edinburgh Public Health Committee had discussed the question of meat inspection, and rather favoured the proposal to have clearing-houses for the inspection of all meat intended for human consumption. The Master Butchers' Association in the city has had a meeting, and has drawn up a memorial to the magistrates and council against this proposal. They consider compulsory inspection an unnecessary harassment of the trade, and they contend that it would be ineffectual in preventing the introduction of diseased meat. They propose severer penalties and a larger detective staff as the best means of discovering and of dealing with culprits. The document is not a convincing one, nor will it satisfy the intelligent public that things ought to be left as they at present are. The proposal of the Public Health Committee may be a novel one, and this, to the Butchers' Association, seems a weighty objection; but with a medical man and a sanitarian in the Lord Provost's chair there is considerable reason why Edinburgh might be in the van of progress in this matter.

Leith Hospital.

The annual meeting of the subscribers to this hospital was held on Monday, Professor Struthers in the chair. The report showed that 91 fewer patients had been treated in the wards than during the preceding year, the total being 883 cases, of which 409 were medical cases, 308 surgical cases, 157 cases of zymotic disease, and 9 submersions. In the dispensary department 8932 patients had been prescribed for and treated at the hospital, 4088 were visited at their own homes, and 232 were visited by the district nurse. There had been a falling off in the subscriptions, and the expenditure for the year exceeded the income. This is one of the general hospitals which continues to provide accommodation for infectious cases, and this has been unfavourably commented upon before. It is now satisfactory to note that the hospital authorities have given notice to the Town Council that they desire to be relieved of the responsibility of these cases, and request them to provide hospital accommodation for them elsewhere. The necessity of providing a special hospital for infectious cases was strongly pressed by the chairman in proposing the adoption of the report, and he hoped the roof would be on the new hospital before their next annual

Digitized by Google

meeting. Professor Struthers was appointed president of the institution.

The Universities Commission.

The ordinance bearing upon assistants and lecturers has been issued. The terms of the Draft Ordinance were referred to at length in the pages of THE LANCET, and it is to be regretted that the Commission has made no material alteration on the ordinance as it was in draft. It perpetuates the present anomalous state of affairs as regards assistants, and provides for lectureships in a manner that will make good men hesitate to apply for them, or even accept them if offered to them.

March 8th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Hospital Sunday Fund.

THE eighteenth annual meeting of the subscribers to the Fund was held on Monday last. The report of the Council for 1891 stated that the total amount to the credit of the Fund for the year was £4159 12*s.* 6*d.*, or a decrease of £196 3*s.* 6*d.* as compared with 1890. The working expenses amounted to £271 5*s.* 2*d.* The Visiting Committee report that many of the defects complained of in hospitals in the previous year have been remedied, but impress upon the authorities of the participating hospitals the necessity of removing the defects which still exist, and have been commented upon by the Visiting Committee. The Council, acting upon their advice, reduced the grants to the Coombe Lying-in Hospital and Mercer's Hospital by £10 and £20 respectively, on account of the dirty condition in which these hospitals were found by the visitors. The Adelaide Hospital received the highest grant (£819 6*s.* 2*d.*), and Mercer's Hospital the lowest—viz., £62 17*s.*

Census for County Tipperary.

The population, according to the recent census of this county, was 173,188, or 13·2 per cent. less than in 1881, while the number of persons returned as receiving relief under the Poor-law was 6215, or 1 in every 28 of the population. The births during the ten years were 40,328, being an average annual rate of 21·6 per 1000, the average yearly rate for the whole of Ireland during the same period being 23·2. The deaths for the decade amounted to 32,951, a number equal to an average annual rate of 17·7 per 1000, while the corresponding rate for the whole of Ireland was 17·8.

Monkstown Hospital.

A memorial ward in memory of the late Duke of Clarence has now been named the "Albert Victor Christian Edward" in this institution. At first it was contemplated to call it the "Clarence Ward," but at the request of H.R.H. the Princess of Wales it was changed. A large portrait of the late prince, in the uniform of the 10th Royal Hussars, will shortly be placed in the ward.

The death is reported of Dr. Abraham Crawford Swayne, J.P., at Carrick-on-Shannon, on the 6th inst., aged seventy-two. The cause of death was influenza.

March 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Prolonged Non-recurrence of Cancer of the Tongue after Ablation.

SOME years ago Mr. A. E. Barker undertook researches into the results of removal of the tongue for epithelioma, and he found that out of 170 cases only seventeen remained free from recurrence one year after the operation. A patient of Mr. Christopher Heath actually remained well for ten years after a very radical operation. Any such exception to the general rule is therefore worthy of record, and the following facts will be found interesting to your readers, emphasising as they do the importance of removing any enlarged glands that may be found in the neighbourhood of the affected organ. On Feb. 10th M. Quenu presented a patient—a gardener—whose tongue had been removed by him in its entirety four years ago for epithelioma. No signs of any return of the disease are now recognisable. On Feb. 17th M. Jalaguier spoke of a patient of his, aged sixty-eight years, who, being affected with cancer of the tongue with adherence to the lower jaw, underwent on Aug. 6th, 1888, the following operation: Excision of half of the diseased organ, of half of the jaw, the submaxillary gland, and of two lymphatic glands. Cicatrisation occurred in six weeks; and the patient, who sends an annual report of his condition to M. Jalaguier, has remained free from any return of the disease since.

Typhoid Fever in the French Army in 1891.

All friends of sanitation who have followed the recent political crisis will be pleased to learn that that very capable administrator, M. de Freycinet, has consented to remain at his post at the Ministry of War. A continuation of the sanitary policy followed by him would bring the number of cases of typhoid fever occurring annually in the ranks of the French army down to a comparatively insignificant figure. From the report just issued we find that wherever it has been possible to substitute pure for polluted water, or where, in default of this, such impure water has been systematically subjected to a filtering process by the Chamberland method, enteric fever has practically disappeared. Thus at the garrisons of Compiègne, Le Mans, Domfront, and eighteen others, which bore an evil reputation in this respect, the disease no longer appears in an epidemic form, only isolated and rare cases occurring. The epidemics which have made such ravages at such places as Montargis, Avesnes, Lisieux, Evreux, Nantes, and Perpignan were all traced to the consumption of water furnished by wells previously condemned as contaminated, or to accidents to municipal water-pipes necessitating recourse to impure drinking-water. This latter accident happened in Paris in January and February of last year, and the consequent consumption of Seine water brought about a serious outbreak of typhoid fever in the garrison of Paris. Notwithstanding these unfavourable circumstances, great progress has been made of late years towards stamping out this curse of French barracks. In 1867 the cases of typhoid fever in the army reached the formidable total of 6881; in 1889 this total had fallen to 4412; in 1890 to 3491; and in 1891 to 3225. That is to say, the number of cases of typhoid fever occurring in the French army have decreased since 1867 52 per cent., a most encouraging state of things. The deaths in 1867 were 864, as against 534 in 1891. It is hoped that the extension of the measures now being taken to provide the men with pure drinking-water will in 1892 have brought down the mortality noted during the years 1886 and 1887 at least 50 per cent., and the number of cases treated 60 per cent. Up to Dec. 31st last, Chamberland filters had been installed in France and Algeria in such numbers as to guarantee ample provision of pure water to 200,000 troops (185,000 in France and 15,000 in Algeria). The hygienic programme undertaken by M. de Freycinet will be complete when provision is similarly made for 45,000 more men. The Minister of War terminates his report by complimenting the Army Medical Service for the manner in which its members have seconded his efforts to render this filth disease a thing of the past in the armies of the Republic.

The Law and the Dieting of Infants.

Patriotic law-makers are very sensitive on the question of the decline of the population and the eventual relegating of France to a, numerically speaking, second- or third-rate position amongst the family of nations. Remedy after remedy has been suggested to stem this decline, but while it is generally felt that the control of human production is beyond the ken of Acts of Parliament, the Code Napoleon can at least be made to serve a purpose in safeguarding the existence of the newly acquired additions to our population. A year ago the Prefect of the Department of Orne enjoined the local practitioners charged with the inspection of the numerous infants which are nursed at the expense of the Assistance Publique, to refuse to give the necessary certificate to any nurse who used in the rearing of her charge a bottle with a tube or who gave the child any form of solid food before it reached the age of one year, unless otherwise ordered by the practitioner. It was one thing, however, to thus threaten the nurses, but it was quite another matter to get them to carry out the order. In their annual report the medical inspectors pointed out to the Prefect the impossibility of getting strict compliance with his order short of a formal local Act or by-law. This has now been enacted, and in the following terms:—It is prohibited

Digitized by Google

(1) to give to infants under one year any form of solid food unless such be ordered by a written prescription signed by a legally qualified medical man; (2) it is further prohibited for the nurses to use, in the rearing of infants confided to their care, at any time or under any pretext whatsoever, a bottle or bottles with tubes. Then follow the penalties which will overtake nurses who do not conform to the above. In the reforms in the law which cannot be long delayed on your side of the Channel on the burning question of infant life assurance and its terrible abuses, note might with advantage be taken of the foregoing life-saving enactment.

March 9th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Sleeping Miner.

THE following details have transpired regarding the state of the German miner, Johann Latos, who slept for four months and a half. At the present time he is in excellent health. The rapid emaciation which set in after his awaking has been completely remedied by suitable nourishment. His mental condition is very satisfactory, and he is able to answer questions put to him. An attendant asked him the other day whether he could remember the beginning of his illness, whereupon he spoke of his first moments of consciousness after awaking. The kidneys are not affected.

Dr. Shibasaburo Kitasato.

Dr. Kitasato, the well-known Japanese bacteriologist, who has been called to direct an institute for infectious diseases belonging to the University of Tokio, has lived for about six years in Berlin. He has occupied himself all the time, under Koch's guidance, with bacteriological research, first at the Hygienic Institute of the University, and since last autumn in the Institute for Infectious Diseases. Not only Koch, but also Löffler (now Professor at Greifswald), has had a share in the training of this most able investigator. Some of his first researches were undertaken at Löffler's suggestion, and carried out with his help. It was not until the winter of 1890 that Kitasato became widely known by his publication, conjointly with Behring, of studies on the production of diphtheria immunity and tetanus immunity. He has recently published communications on the cultivation of the influenza bacillus, and important new observations with reference to the cultivation and vitality of the tubercle bacillus. It is interesting to observe that Kitasato is not the only Japanese who has distinguished himself in bacteriology; his countrymen, Ogata, Kumagawa, and Miura are worthy fellow-labourers in that vineyard.

An International Clinical Interpreter.

The Berlin firm of Hepner and Co. has published the first part of a book entitled "Internationaler Lazareth-Sprachführer" ("International Clinical Interpreter"), by Paul Blaschke, containing not only the most necessary medical words and expressions, but also the natural questions and answers between doctor and patient. The first part is in German and French, and its purpose is to enable doctors and attendants who cannot speak French to understand French patients and make themselves intelligible to them as far as is practicable

Professor Kussmaul.

On the occasion of his seventieth birthday, on the 22nd ult., Professor Kussmaul made over the sum of 10,000 marks (nearly £500) to the Louisa Hospital at Heidelberg. The fund is to bear the name "Hedwig Kussmaul Fund," in memory of a daughter of the founder who died as a child.

The Leuton Prize (5000 fr.) has been awarded to Dr. Theodor Landau of Berlin, assistant in Dr. Leopold Landau's private clinic for diseases of women.

Berlin, March 8th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Medical Literature for 1891.

IN setting out to chronicle the literature of these colonies for the past year, one is tempted to use the laconic style of the historian of "Snakes in Iceland," and write "there is no Australian medical literature." In a measure such a description would be true. The only work of any note professing to deal with a subject peculiarly Australian is Dr. Graham's monograph on Hydatid Disease, which may well be consulted by all interested in parasitic disorders. Truth to say, there is very little original research done in Australia. Scientific work does not pay, and the laity do not understand it. As in all new countries, the *auri sacra fames* is here the guiding motive, and any work that does not bring gold as a result is pushed aside. Perhaps the most interesting work of the year has been the testing of strychnine as an antidote to the virus of snake bite. Dr. Meuller of Tackandandah, Victoria, is, however, not *propheta in patria sua*, for the Victorians do not admit his claim to the discovery of the strychnine method of treatment. Moreover, Dr. Bancroft of Brisbane is doubtful of the results of the treatment. As the readers of THE LANCET had recently an opportunity of studying the physiological part of the question through an article by Dr. Meuller himself, I will not touch on that subject. As regards the treatment of snake bite by hypodermic injections of strychnine, it may be said at the outset that there is abundance of evidence that cases so treated have recovered. There is also evidence showing that in some cases—as, for instance, in the Prince Alfred Hospital, Sydney—the strychnine remedy has failed to prevent a fatal termination. With contradictory results it is impossible to accept strychnine as the physiological antidote of snake poison. Dr. Bancroft puts his finger on the weak part of Dr. Meuller's argument in favour of strychnine when he shows that a large number of Australian snakes are not at all venomous, and that persons bitten by such snakes would get well under any treatment, or without any treatment at all. Up to the present the investigation has been carried on in a most unscientific manner, hence the results cannot be relied upon. Dr. Ross of Warranambool, Victoria, published during the year in the *Medical Journal* various papers on the "Moulds and Yeasts as Morbific Agents." I referred to Dr. Ross' discovery of a mycotic form of pneumonia in a former communication, and will just say here that further investigations, not yet completed, show that nephro-mycosis and mycosis of other organs are not at all uncommon in Victoria. Strangely enough, while Dr. Ross is investigating the yeasts from the disease-producing point of view, M. de Bavy, a Melbourne bacteriologist, claims to have discovered that yeast is a disease destroyer akin to the phagocyte of Metchnikoff. How far this claim will bear investigation remains to be seen. As might have been expected in a country which has become the dumping ground for the consumptives of the Old World, Koch's method of treatment has been extensively tried. One of the physicians to the Melbourne Hospital (*Kochior Kochio ipso*) published a string of cures—I do not remember if he had a failure; but bearing in mind Professor Virchow's dictum on the matter, I shall wait for another year before giving details of the results attained here by Dr. Koch's method of treatment. The most useful and interesting paper read at any of the societies during the year was one on Typhlitis, by Dr. G. A. Syme, F.R.C.S. Eng., before the Melbourne Medical Society, which gave rise to an animated and instructive discussion. On the whole the year 1891 was very barren of original work.

The Increase of Medical Clubs.

At the annual meeting of the Victorian Medical Society held in Melbourne this month, Dr. Hinchcliff, the retiring president, adverting to the club system, stated that it was so much on the increase that before very long the whole population would belong to clubs.

Jan. 24th.

BURTON-ON-TRENT GENERAL INFIRMARY.—The twenty-second annual report, 1891, just issued, shows a marked increase on the number of both in- and out-patients over the totals of the preceding twelve months, and, with one exception, the largest number of in-patients yet admitted in any one year. The annual subscriptions have been fully maintained. The year's Sunday collection was more by upwards of £31, and the Saturday committee had successfully exerted themselves to keep up the amount of their contributions, without which, it is stated, it would be difficult to carry on the infirmary, forming, as they do, so large a proportion of the total receipts.

Obituary.

PROFESSOR JAMES ROSS, M.D., LL.D., F.R.C.P.

BY the death of Dr. James Ross, which took place at his residence in Manchester on Feb. 25th, from cancer of the stomach, we deplore the loss not only of a most distinguished physician and teacher of medicine, but of one of the foremost of English neurologists, whose fame had extended far beyond the borders of England, and whose name and works were known all over the scientific world.

Dr. Ross was the third son of Mr. John Ross, farmer, and was born at Kingussie on Jan. 11th, 1837. Educated at the parish school at Laggan, it was intended that he should follow the teaching profession, and with this end in view he went to Edinburgh to attend the Normal School, and for a time was locum tenens for the teacher at the East Free Church School, and many of his pupils still recall to memory the gentle lad who took their teacher's place. Destitute of the sterner qualities required to govern a set of rough lads, he resolved to quit the teaching profession, and turned his thoughts to medicine. After having studied pharmacy under Messrs. Shield and Mill at Arbroath, he went to Aberdeen for his medical studies, where he passed through a very distinguished curriculum. Besides medicine, the study of philosophy and metaphysics had special charms for him, and this, no doubt, laid the foundation for his subsequent career and line of work. After having made two voyages in a Greenland whaler he came to England in 1863, where he began practice as assistant to the late Dr. Bywater at Knottingley, who was ill at the time, and died in November, 1863. Dr. Ross, with characteristic self-denial, carried on the practice for two years, to the greatest satisfaction of the patients, till the son of his late principal became qualified. He then, after having been at Burnley (Lancashire) for some months, started practice at Waterfoot, in the Rossendale valley, where he succeeded Dr. Crabtree, and where he soon became a very busy and popular general practitioner. In 1869 he married Miss Bolton, niece to the late Dr. Crabtree. In spite of a large practice he still found time for literary work, and, besides a number of papers in the *Practitioner*, he published some remarkable essays, of which the one on Protoplasm and the one on the Graft Theory of Disease, subjects which at that time, chiefly through the writings of Huxley, caused a good deal of stir in the scientific world, became more widely known. Those who knew Dr. Ross will understand how deeply he would at times become absorbed in philosophical thoughts even in the busy round of country practice, and he had, whilst going his round to his patients on horseback, many narrow escapes from the horse getting astray or the reins becoming entangled; and on one occasion, when he paid an evening visit on horseback to a patient, he forgot all about his horse, which he left in front of the patient's house, and walked home on foot a distance of several miles. His love for scientific work was so great that he decided to relinquish the large and lucrative practice at Waterfoot, much to the regret of his numerous patients and friends, and went to Manchester in April, 1876, where in August of the same year he was appointed pathologist to the Royal Infirmary. He was also elected physician to the Children's Department of the Southern Hospital for Diseases of Women and Children, but held the post only for two years. As pathologist, though already nearly forty years old, he worked with surprising enthusiasm and zeal, and following partly his own natural inclinations and partly the events of the time—as about this period the study of the diseases of the nervous system received such great impetus from the important researches of English and continental observers—he devoted himself chiefly, but not exclusively, to the study of nervous diseases. In October, 1878, he was appointed assistant physician to the Manchester Infirmary, and soon became a very popular teacher. Having as yet no large consulting practice, he devoted a good deal of his time to collecting materials for his great work, "A Treatise on the Diseases of the Nervous System," which appeared in 1881, a work which was not only a compilation of all that was known on the diseases of the nervous system at that time, but which contained also a great many original observations and new views on many subjects—viz., on the functions of the ganglia cells in Clark's columns, on the origin and relations of the nerve nuclei in the medulla, &c.—which were confirmed by subsequent observers. This treatise made its author at once famous, received the most favourable criticism on all hands, and was so much in demand that a second edition appeared in 1883. Dr. Ross became a Fellow of the Royal College of Physicians in 1882, and his *alma mater* conferred on him the honorary LL.D. degree in 1883. Acceding to the request of an American publishing firm, Dr. Ross wrote his "Handbook on the Diseases of the Nervous System," which was published in 1885, and which, shorter and more concise than his great work, at once became popular. In the meantime Dr. Ross's consulting practice had much increased, and extended over a very large area. He found, however, still time for much original work, and his excellent clinical teaching attracted a large number of students. In 1887 he was appointed Co-Professor of Medicine at Owens College, taking the lectures on the diseases of the nervous system, the rest of the course being given by Professor Morgan, who, to the regret of all, has recently resigned his chair, owing to ill health. In 1888 Dr. Ross succeeded to the full physicianship of the infirmary, which gave him further facilities for clinical teaching and observations. His increasing consulting practice put some check on his literary activity, which is much to be regretted, as on some subjects—e.g., traumatic neurosis—he held new and original views, which well deserved to have been placed on record. In the winter of 1890 his health began to fail, and he himself was the first to suspect his symptoms to be due to malignant disease of the stomach; but as he had suffered before from nervous dyspepsia, and as there were no physical signs of a malignant growth, he tried for a time change of air, and then underwent treatment with massage and forced feeding. He returned to Manchester in the beginning of this year, evidently suffering from malignant disease. He, however, bravely struggled on with his private and hospital work for a few weeks; but, alas, the fatal termination came sooner than expected. He was conscious to the last, and died peacefully and resigned.

Of his great merits as a practical and scientific physician, as a clinical teacher, and as a writer and original thinker, and of his sterling qualities and his private character, it is impossible to speak too highly. Though his publications refer chiefly to the nervous system, yet he had a most extensive and profound knowledge of medicine generally and of the collateral sciences. As a clinical teacher he will not be easily surpassed; though naturally a very quick observer and diagnostician, in his teaching he was methodical, clear, and exact; he impressed his hearers very much, and incited his students to original work. His contributions to medicine are numerous; his earlier publications refer chiefly to therapeutics. In his later papers he occupied himself almost exclusively with neurological subjects. His writings bear the stamp of accurate clinical observation, of deep philosophical thought, and of great originality. The following are the titles of some of the works which proceeded from his pen, in addition to those published in medical journals: "On Counter-irritation: a Theory constructed on the Deductive Method of Investigation" (Lond., 1869); "The Graft Theory of Disease; being an application of Mr. Darwin's Hypothesis of Pangenesis to the Explanation of the Phenomena of the Zymotic Diseases" (Lond., 1872); "On Protoplasm; being an Examination of Dr. James Hutchinson Sterling's Criticism of Professor Huxley's Views" (Lond., 1874); "On Aphasia; being a Contribution to the subject of the Dissolution of Speech from Cerebral Disease" (Lond., 1887); "Technical Education": an Address (Manchester, 1889); "On Evolution": an Address (Manchester, 1888). As a writer he was clear and precise, and in some of his philosophical papers, as in that on Evolution, his style and language are exquisite. His papers comprise the various subjects of Neurology, from the peripheral nerves to the highest nerve-centres. Of the more important ones we may cite the papers on Peripheral Neuritis (published in the *Medical Chronicle*), which his premature death prevented him from completing, but which will remain for many years as the best and most complete treatise on this interesting affection, and a masterpiece of accurate clinical observation. The paper on the "Segmental Distribution of Sensory Disorders" is a truly remarkable production; it shows its author to have been conversant with the most recent researches in anatomy,

Digitized by Google

physiology, and embryology; it gives proof of his general knowledge of medicine and of his faculty of generalisation. The subject matter of this contribution forms a valuable diagnostic aid to many affections besides those of the nervous system, and its importance has not as yet been sufficiently recognised by the medical world. The collected papers on Aphasia show that even a subject which had been exhaustively treated by many before him still presented to him, the psychologist and philosopher, new points for elucidation. Dr. Ross was not afraid to attack the most difficult subjects. In proof of this we may refer to his address on Evolution (which is described by an able critic as "the concession of a cultivated scientist to the demands of a religious idealism") and the last of his papers, on Memory, read before the Neurological Society when his health was already impaired and the first signs of his fatal disease had shown themselves.

This sketch would not be complete without alluding to Dr. Ross's private character. He was singularly modest and unobtrusive, a man of sterling honesty and kindly disposition. His death has cast a gloom over the whole district in which he had so many friends, both amongst the poor and the rich, the lay and the medical world, for to all he endeared himself by his lovable qualities; and no one appealed to him in vain for advice or assistance.

GEORGE YEOMAN HEATH, M.B.LOND., F.R.C.S.ENG., NEWCASTLE-ON-TYNE.

FOR some months past the friends of Dr. Heath have been aware that he was not in a satisfactory state of health. For one thing he suffered from arthritis of the hip, which much hindered his walking power. But more seriously he suffered from somewhat vague hepatic symptoms, sometimes like those of gallstone, and at others having more the aspect of grave hepatic disease. He was present at the November meeting of the General Medical Council, where he ably represented the University of Durham. At the previous meeting he was only present once, being unable to attend from illness. But in November he displayed his usual animation in the society of friends, in discussing questions not only in surgery, which always lighted up his face, but in general literature and modern thought, with great personal force. His last illness, which terminated fatally at his residence, Cocken Hall, near Durham, on Friday, March 4th, had lasted about seven weeks, and was noticed in our Northern Counties Notes.

It will not be regarded as any disparagement of his colleagues to say that Dr. Heath was the *facile princeps* of surgery in Newcastle-on-Tyne and in the adjoining counties. There was in him a combination of personal qualities which is rarely found, and which—together with his education in the school of Liston, whose house surgeon he was at University College, whose methods he learnt and followed so well, and whose gold medal in surgery he took—made him a model surgeon, firm and cunning of hand, quick of eye, ready in resource, and open to all the lights of modern teaching. There was a certain irascibility about him as there is often about men of strong individuality of character. But in the general intercourse of his profession he was extremely courteous and agreeable, and in the debates of the Council he displayed a modesty and reticence which obscured the range of his knowledge and his vast experience. Dr. Heath was no mere specialist in surgery, but was equal to every duty. He was for more than a generation surgeon to the Newcastle Infirmary, whose environment secured a rare variety and range of surgical cases. He was, however, remarkably successful in lithotomy. He had performed 104 lithotomies before he learnt the more excellent way of lithotrity. He was for many years surgeon to the Eye Infirmary of Newcastle. On the occasion of the meeting of the British Medical Association in Newcastle in 1870 Dr. Heath was selected to give the Address in Surgery. He expatiated with great eloquence and effect on what he called the three characteristics of modern operative surgery—its *audacity*, its *conservatism*, and its *success*. And he did so with such wealth and pith of illustration as would not ill become an address in surgery now.

Dr. Heath's reputation in the profession is to be gathered from another incident in his history—the gift of the Fellowship of the Royal College of Surgeons of England in 1886. This compliment of the College gave him much pleasure, but it gave still more to his students and his colleagues. The University of Durham conferred on him the degree of D.C.L. His interest in the practice of surgery scarcely exceeded his interest in the teaching of it and in the discussion of methods of medical education. He was connected most intimately and almost affectionately with the School of Medicine in Newcastle, both before and after its junction with the Durham University. In a most interesting history of this Medical School by that veteran of the profession, still vigorous with octogenarian strength, Dr. Embleton, there is a list of students of the school in 1839–40, including Dr. Heath's name. In the list of lecturers in the school for 1845–46 his name appears jointly with Mr. Potter's as lecturer on the Principles and Practice of Surgery, and ever since then his interest in the school has been an element of its strength. When the school became a college of medicine in connexion with the University of Durham, Dr. Heath appeared with his brother, Mr. Henry Heath, as joint lecturer on the Principles and Practice of Surgery. On the death of Dr. Charlton he was made President of the College, and continued so till his death. Visitors to Newcastle will recall the pride and pleasure with which he was wont to show them over the new handsome and commodious buildings, which constitutes a feature in the modern architecture of Newcastle. He showed his feeling, too, in a more substantial way by the gift of a thousand guineas towards its cost.

Dr. Heath was born in Westoe, a village hard by South Shields, where his father, Mr. Heath, lived. On his mother's side he was related to Dr. Winterbottom of Westoe, formerly physician to the Colony of Sierra Leone, and author of a classical book on the "Diseases of the Natives of Africa." We are not favoured with any account of his school-days, but a very slight acquaintance with him was enough to show that he was a man of great general culture and knowledge. His early medical education began, as was the fashion in those days, in apprenticeship to his brother Henry, who was surgeon to many neighbouring collieries. This experience was gratefully remembered by Dr. Heath in after years, and moved him to speak in the Medical Council in favour of some form of pupilage. After studying in Newcastle, at University College, London, and Paris, and after graduating M.B. in London, he returned to Newcastle and began the career of practice and of teaching which has made him one of the most conspicuous figures in the medical history of that ancient and famous city, and the termination of which, even at the age of over threescore years and ten, leaves men with a sense of blank and loss expressed to us well by a colleague: "We shall miss Heath very much; his place will not be filled."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the Royal College of Surgeons held on the 10th inst., the minutes of the ordinary meeting of the 11th of February were read and confirmed.

The name of a Member was removed from the roll of the College for infringement of the By-laws, Clause 5, Section 17.

A letter of the 15th ultimo from the Secretary of State for Home Affairs was read, stating that Her Majesty had been pleased to receive very graciously the Address of the College on the occasion of the death of his Royal Highness the Duke of Clarence and Avondale, K.G.

A report, dated Feb. 15th, 1892, from the Committee of Management and the Treasurers of the Royal Colleges on the arrangement of fees under the five years' curriculum, was read and entered on the minutes. By this report it is agreed by both Colleges that the fees for the conjoint examinations shall remain as at present; they will, however, be differently disposed as regards the final examinations.

On the report of the Committee of Management the synopses of the subjects of the first and second examinations under the regulations of the five years' curriculum were agreed to. The one relating to Elementary Biology was prepared after consultation with several of the teachers. The existing synopsis of Chemistry, Physics, and Practical

Digitized by Google

Chemistry has been altered to a small extent, at the suggestion of the examiners, and the synopsis of Practical Pharmacy has been completely rewritten with the assistance of the examiners. The Committee do not recommend any alteration in the existing synopses of Elementary Anatomy and of Physiology.

The following resolution of the Council was carried *nem. con.*:—"That the Council, after full consideration of the infraction of Section 17 of the by-laws by certain Members of the College, who took part in an attempt to convene an illegal meeting for the 28th of February, 1889, hereby determine to take no further action in the matter."

The President stated that he had accepted, on behalf of the Council, a bust, by W. M. Kemp, of the late Mr. John Gay, past member of the Council, presented by his widow Mrs. Gay. The best thanks of the Council were given to Mrs. Gay for her gift.

A letter was read from Mr. Morrant Baker resigning his post as examiner to the College. The vacancy thus caused will be filled at the next meeting of the Council on April 7th.

Sir W. Savory moved, and Mr. Macnamara seconded, a resolution, which was agreed to: "That a committee be appointed to consider and report to the Council whether any, and if so what, further advantages can be extended to the Fellows." The members of the committee appointed are Sir W. Savory, Bart., Messrs. Cadge, Macnamara, Willett, and Rivington.

Mr. Willett moved, and Sir W. Savory seconded, the following resolution:—"That it is desirable to celebrate in some suitable manner the fiftieth anniversary of the institution of the Fellowship of this College (the Charter creating this order being dated Sept. 14th, 1843), and that a committee be appointed to report on the best means of giving effect to this resolution." This was agreed to, and referred to the same committee.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen, having passed the necessary examinations and conformed to the by-laws and regulations, were at a meeting of the College on March 3rd admitted Licentiates:—

Mackinnon, Andrew Robertson, M.R.C.S., University of Aberdeen.
Reid, Mathew Alexander, M.R.C.S., University of Edinburgh.
Smyth, Reginald Mander, M.R.C.S., St. Mary's Hospital.
Stack, Edward Hugh Edwards, M.R.C.S., University of Cambridge and St. Bartholomew's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations, and conformed to the by-laws and regulations, were, at an ordinary meeting of the Council on the 10th inst., admitted Members of the College:—

Howe, George Bradley, L.S.A., Owens College and Royal Infirmary, Manchester.
Prosser-Evans, Jehosophat, L.R.C.P. Lond., University College Hospital.

ROYAL FREE HOSPITAL.—On Thursday, the 3rd inst., Mr. Mackellar presented, on behalf of the past and present residents of the Royal Free Hospital, an address to Mr. F. J. Gant on his appointment as consulting surgeon to the institution. The delay in making the presentation was owing to the difficulty in obtaining the signatures of such a large and scattered body of medical men. The address, which was given after a graceful speech, was as follows:—"We, the undersigned past and present resident medical officers of the Royal Free Hospital, desire to express to Mr. Gant, upon his retirement from the post of senior surgeon, our sincere regret at his withdrawal from the active staff, and to tender him our hearty congratulations on his completion of over thirty-seven years' connexion with the institution. The great services which Mr. Gant has rendered to the hospital and to surgical science by his published works are well known to all. We are able and privileged to express our hearty appreciation of his excellent qualities in his personal relation to us as our senior surgeon and chief. In Mr. Gant we have at all times found a most sterling and sincere friend." Mr. Gant feelingly replied. Mr. Ford North was in the chair, and members of the weekly board, of the hospital staff, and students were present. Mr. Gant had already received addresses from the hospital committee, the students, and the nursing staff.

THE PRUDENTIAL ASSURANCE SOCIETY.—The quinquennial report of the Prudential Assurance Company states that during the past five years the assets of the company had grown from £6,811,954 to £14,623,627, being an increase of £7,811,673. The annual premium income amounts to £5,386,990.

CHILDREN'S HOSPITAL, BRIGHTON.—The twenty-third annual report states that during the year 1891 348 children were treated in the hospital, and the out-patients numbered 2842. The balance-sheet shows a deficit of £231 13*s.* 9*d.*, which have been partly provided for by the withdrawal of about £200 from the savings bank. A considerable outlay is at the present time needed, owing to the growing demands upon the charity, and it was felt, especially by the medical staff, that provision for convalescent accommodation was a necessity.

ROYAL PORTSMOUTH HOSPITAL.—The annual meeting of this deserving institution was held at the town hall on the 23rd ult. Mr. J. Pares, J.P., occupied the chair. The Duke of Connaught and a numerous and influential assembly attended. The total number of persons deriving benefit from the charity during 1891 was 7825. The balance against the hospital on the year's work in respect of the ordinary sources of income and expenditure was £991 15*s.* 5*d.* His Royal Highness, on proposing a vote of thanks to the honorary medical staff, remarked on the great value of such an institution to a town like Portsmouth, and the admirable services of the medical staff.

ROYAL SURREY COUNTY HOSPITAL.—This charity continues to enlarge its sphere of usefulness. The report for 1891 shows that there had been an addition on the previous twelve months to the number of in-patients treated, and about the same total of out-patients as in 1890. The receipts were £4257 1*s.* 5*d.*, showing a small increase, but, owing to unavoidable additions to the expenditure, the income was exceeded by £245, the total disbursements amounting to £4502 4*s.* 10*d.* Funds were specially required to enable the committee to open a second ward in the new wing, the expense of which would be from £300 to £400 per annum.

ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held at 25, Great George-street, Westminster, on the 16th inst., at 7 P.M., the president, Dr. C. Theodore Williams, will deliver an address on "The Value of Meteorological Instruments in the Selection of Health Resorts," which will be illustrated by a number of lantern slides. The meeting will be adjourned at 8.30 P.M. in order to afford the Fellows and their friends an opportunity of inspecting the exhibition of instruments, charts, maps, and photographs relating to climatology, and of such new instruments as have been invented or first constructed since the last exhibition. The exhibition will be open from Tuesday, the 15th inst., to Friday, the 18th.

CHELTENHAM EYE, EAR, AND THROAT INFIRMARY.—The second annual meeting of this infirmary was held on March 1st at the Cheltenham Assembly Room. By the report it appeared that there was a deficit of some £64 on the year's working, but the hope was expressed that the amount would disappear in 1892. The honorary surgeon, Dr. F. A. A. Smith, M.D., C.M., said that during the first year they had treated 720 patients—31 in-patients and 687 out-patients. The number of attendances was 3656, with 219 operations. Comparing these figures with those given in the present report, during the past year they had admitted 42 in-patients, all serious cases, and treated 709 out-patients, while the number of attendances had been 4418, and of operations 246.

A COMPLIMENTARY DINNER.—Dr. S. M. P. Roberts, lately senior physician to the Public Hospital and Dispensary, Sheffield, has been entertained at a dinner at the Wharncliffe Hotel by a large number of friends on the occasion of his leaving the town to practise at Beckenham. Mr. W. Fisher Favell occupied the chair. There was a large attendance of the leading practitioners of Sheffield and the neighbourhood. Dr. J. H. Keeling proposed the toast of the evening, "The Health of Dr. Roberts," expressing the high sense entertained of his earnest work for the public hospital and medical school, his loyalty to those with whom he worked, and his untiring energy in promoting the building of the new hospital.

Digitized by Google

SUNDAY LECTURE SOCIETY.—Dr. Benjamin W. Richardson, F.R.S., is announced to lecture on "Pestilences in England, Ancient and Modern, their History, Causes, and Prevention," at Langham-place on Sunday next, at four o'clock, instead of Dr. Klein, invalided.

LITERARY INTELLIGENCE. — Messrs. Longmans announce as in the press a new work by G. J. Romanes, M.A., LL.D., entitled "Darwin and after Darwin," an exposition of the Darwinian theory, and a discussion of post-Darwinian questions.—We have received a specimen copy of the International Medical Magazine, a new monthly published by J. B. Lippincott, Philadelphia, and edited by Judson Daland, M.D.

LIVERPOOL STANLEY HOSPITAL.—The report for 1891 just circulated shows that the number of in-patients was in excess of any former year except the year 1889. In the out-door department 11,123 patients were treated, and the attendances were 34,667. During the year there had been a large increase in the number of subscribers. The adverse balance brought forward from the previous year had been reduced by donations to £445.

THE DENTAL HOSPITAL OF LONDON.—The thirty-fourth annual meeting of this institution was held at the hospital, Leicester-square, on the 10th inst. The report stated that in consequence of the ever increasing number of patients it had been decided to open all the departments of the hospital in the afternoon. A subcommittee had been appointed to consider the advisability of additions to, or alterations of the present accommodation. The managing committee pointed out that there had been many losses by death, and, as the charity was unendowed, additional funds would enable it greatly to extend its usefulness.

THE LONDON SANITARY PROTECTION ASSOCIATION. The report of the council for 1891 shows a further increase of members; 477 new members had joined during the year. On the other hand, 455 members withdrew. The total membership at the end of the year was 1613, an increase of twenty-two on the previous twelve months; 475 houses were inspected for the first time in the course of the year, and the special inspections numbered 486, against 457 in 1890. The council again report that no application was received for sanitary inspection of the dwellings of the working classes throughout London. The cash statement showed a balance in hand of £703 5*s.* 2*d.*

FOOTBALL CASUALTIES.—In a match at Devizes recently between the Devizes Recreation Club and Trowbridge a player fractured his clavicle.—On the 20th ult., during a game played at Lurgan between the Newry Wanderers and a local team, a youth (one of the former) sustained a bad fracture of the right leg "below the knee," and was conveyed to the infirmary, where he remained under treatment.—On the same day, whilst playing at Farsley, with the Thornhill Lees Trinity against Farsley, a Dewsbury three-quarter back "sprained the muscles of one of his thighs." He was carried to the Farsley headquarters, and received medical assistance.—On Saturday, during a game between the Gala Second and Hawick Second at Mossilie, a young man who played for Hawick fractured his leg.—On the same day, in a match at Goole between the Goole and the Wakefield Trinity (second teams), a player was badly injured. Medical assistance was obtained, when it was found he had sustained a serious injury in the groin, and was removed to the Goole Cottage Hospital; and at Linthorpe, whilst playing in a match—Middlesbrough Vulcan and Newport Excelsior—a Vulcan forward had his "nose broken."—On Saturday, during a game at Kingsholme between Gloucester and Exeter, a Gloucester three-quarter back collided with the Exeter back and was picked up in an unconscious state. He was taken to the infirmary, and on examination was found to be suffering from concussion of the brain.—On the same day, whilst playing at Winchcombe in an Association match between the Evesham Wanderers and Winchcombe, one of the Evesham backs "sprained his ankle and severely wrenched the muscles and tendons"; and a young man playing in a game at Acton fractured his clavicle and was removed to the University Hospital. Also, in a match played at Crewe between Alexandra Hornets and Nantwich, a Nantwich forward fractured his leg.

THE DENTAL HOSPITAL ATHLETIC CLUB.—Mr. Morton Smale, dean of the Dental Hospital of London, presided at the annual dinner of this association, held at the Holborn Restaurant on Saturday last. The secretary, Mr. Pike, said that the finances of the club showed a balance on the sunny side, and in the field its record was one of success.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—The report for 1891 of this hospital is highly satisfactory; 436 more patients had received treatment than during the previous year. The separate attendances numbered 56,340. The year's income from all sources was £2655, against £2272 in 1890, but legacies amounting to £516 10*s.* had come to hand, and had averted a deficit.

ROYAL BERKSHIRE HOSPITAL. — The fifty-third annual court of governors was held on the 23rd ult. This hospital receives patients not only from the town of Reading but from Berkshire, and many districts in Oxfordshire, Hampshire, and other neighbouring counties. The number of in- and out-patients treated during the past year was 1145 and 1687 respectively. Additional accommodation for the nurses had been provided. The treasurer's report showed that the year had been remarkable as regards income. Donations had been received by which the ordinary receipts were raised to £8486, being £2100 more than in 1890. The total expenditure amounted to £7069.

VOLUNTEER MEDICAL OFFICERS' DINNER. — Brigade-Surgeon Lieutenant-Colonel Wills, Mersey Infantry Volunteer Brigade, presided at the dinner of the officers of the medical staffs of the volunteer service of the City (D. District), held at the Adelphi Hotel on Feb. 25th. The guests of the evening were Fleet-Surgeon Woods, R.N., H.M.S. *Eagle*, and Brigade-Surgeon Lieutenant-Colonel Nicolson of Seaforth. There was a good attendance, and the meeting was a great success, largely due to the admirable arrangements of Surgeons-Captain Barnes of Greenwich, mess presidents of the committee of management.

ESSEX AND COLCHESTER GENERAL HOSPITAL.—The annual report for 1891 records a marked addition to the public utility of this institution. The admission of both in- and out-patients exceeded any preceding year since the foundation of the hospital. The cash statement shows that £149 3*s.* 5*d.* was due to the treasurer. It is worthy of notice that as it is now four years since the experiment was tried of electing a physician, at a salary of £200 a year, to do the whole medical work, so far, the result proves that the appointment has, in all respects, been highly satisfactory.

DELANCEY FEVER HOSPITAL, CHELTENHAM.—The past year's report states that during the previous four years there had not been a single case of small-pox in the town; 71 cases of scarlet fever, more severe than usual, were treated, yet the mortality was small—not 3 per cent. The fees for patients were proportionally greater in the last year in consequence of an increase in the charge per day for patients in the public wards—a change rendered necessary by the town council still withholding their annual subsidy of £100, and refusing the payment of £300, which is stated to be undoubtedly due to the hospital funds. Notwithstanding a large accession during the year in the number of subscribers, the amount still falls much below the sum required for the efficient working of the hospital.

SEAMEN'S HOSPITAL SOCIETY, GREENWICH.—The annual report (the seventy-first) for the past year shows that the number of patients treated in all the establishments of the Society was larger than in any year since the foundation of the charity. It exceeded the average number of the last five years by 872 in-patients and 3000 out-patients. An excess of expenditure over the income during the year, amounting to £2479 5*s.*, had necessitated a draft on the capital fund of £3500. As to the proposed branch hospital in the neighbourhood of the Tilbury Docks, the committee reported that an offer had been received of an eligible building, free of cost, together with £390, towards the preliminary expenses, but they did not think it advisable, in the present financial position of the charity, to take any steps in the matter, unless adequate funds were forthcoming to meet the large prospective outlay.

Digitized by Google

THE LIVERPOOL DISPENSARIES.—During the past year the total number of patients treated at the North, South, and East Dispensaries was 62,245, and the attendances showed a total of 174,659. There had been a considerable falling off of patients in 1891 as compared with the previous year, caused, to some extent, in a natural annual variation, but more particularly in the continued advance of sanitation, and the extensive demolition of insanitary dwellings. Patients had themselves contributed during the year over £1000.

UNITED HOSPITALS' ATHLETIC CLUB.—By the kind permission of the committee of the Lyric Club a concert in aid of the United Hospitals' Athletic Club will be held in the theatre of the Lyric Club, Coventry-street, on the 23rd inst., at 8.30 P.M. The entertainment will include songs, recitations, a short play, and a banjo quartette. Miss Henden Warde, Mr. Norman Salmond, Mr. Charles Bertram, Mr. Richard Green, Mr. Helmore, and Slaverdale's Banjo Quartette, have already kindly consented to appear. Tickets, 5*s.* each, may be had of Mr. Green, St. Bartholomew's Hospital, and of Mr. J. G. Turner, St. Thomas's Hospital.

EAST LONDON NURSING SOCIETY.—The Lord Mayor presided at the annual meeting held at the Mansion House on the 26th ult. The object of the society is to nurse the sick poor of the whole of East London in their own homes by means of trained nurses. At present the society is only able to provide for little more than one-fourth by sending nurses to twenty-eight parishes, comprising a population of 250,000. The staff at present consists of four matrons and twenty-eight nurses, and last year they nursed 3971 persons. The society was affiliated with the Queen Victoria's Jubilee Institute for Nurses early in the year. The year's financial position shows a deficiency of about £150. The Lord Mayor pointed out the benevolent work of the institution, and urged its claims upon the liberal support of the public. The report was adopted.

METROPOLITAN ASYLUMS BOARD.

MEDICAL NOTES IN PARLIAMENT.

Army Medical Department.

IN the House of Commons, on Monday last, Mr. E. Stanhope, in stating the Army Estimates for next year's expenditure, went in detail over some of the requirements of the army. Speaking of the Medical Department, he said: "The strength of the Army Medical Department has been very carefully reconsidered, and considerable reductions have taken place. The assistance of civil practitioners has been called in, and an Army Medical Reserve was formed in 1888, with the view of supplementing the reduced medical staff by a body of officers available for service at home in time of emergency. Very much time has been devoted to the arrangements necessary in case of mobilisation for the medical service, and the arrangements for the *personnel*, the medical equipment, and the necessary base hospitals have been almost completed."

Queen's College, Belfast.

In answer to Mr. Sexton, the Attorney-General for Ireland said that the President of Queen's College, Belfast, had reported that full provision was made in that institution for the instruction of students in anatomy, and that there was nothing to oblige them to attend Dublin in order to obtain subjects for dissection.

Foot-and-Mouth Disease.

Mr. Chaplin, in answer to Mr. Beach, said that the outbreak which occurred in Surrey was believed to have had its origin at Aldershot, one of the places to which some of the beasts, amongst which the disease was originally discovered, were sent down from the London market on the date of the first appearance of the disease. Under these circumstances the movement of animals out of Hampshire was prohibited.

Birmingham Corporation Water Bill.

On Tuesday, March 8th, Mr. Chamberlain moved the second reading of this Bill, which proposes to obtain a supply of pure water from Wales, from the sources of the Elan and the Claerwen, two small tributaries of the Wye. By this means it was intended to provide for the wants of the city of Birmingham and the important towns, villages, and hamlets all along the route for fifteen miles on either side of the aqueduct. This would possibly include supplying such towns of importance as Wolverhampton, Worcester, West Bromwich, and Wednesbury, altogether possessing a population of about a million and a quarter. After a lengthy discussion Mr. Ritchie said the second reading had been opposed from two points of view—the one that of Wales, and the other that of London. If the water-supply of the district were sufficient, it was essentially a matter for representation to a committee, which might succeed in arriving at an understanding satisfactory alike to London, to Birmingham, and to Wales. The House divided, and the second reading was carried by a majority of 142.

Police and Sanitary Regulations Bill.

Mr. Stuart-Wortley moved that all private Bills relating to police and sanitary regulations should be referred to a committee of nine members appointed by the Committee of Selection. The motion was agreed to.

The Gresham University.

In the House of Commons, on Thursday, Mr. Bartley asked the First Lord of the Treasury whether, in the event of the Draft Charter of the Gresham University being referred back to the Privy Council, it was understood that it would be brought before a Royal Commission.—Mr. Balfour said his answer was in the affirmative. If the House referred the Charter to the Privy Council it would be on the understanding that it should be subsequently referred to a Royal Commission. The Commission must be a new one, because the old Commission had come to an end, and care would be taken to make it a strong one. It must not, however, be taken that members of the old Commission would not be asked to stand.—Sir Albert Rollit asked whether the Commission would inquire into the whole question of University education.—Mr. Balfour thought that would be too large a reference. At the same time, very full powers should be given the Commission. Their object was to have a Teaching University worthy of London.

Plumbers' Registration Bill.

The Committee of the House of Commons on this Bill met for the first time on Thursday. They appointed as their chairman Mr. Lees Knowles, and arranged to begin work on Wednesday of next week.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

DEATH CERTIFICATION BY UNQUALIFIED ASSISTANTS.—THE RESPONSIBILITY OF THE PRINCIPAL.

Opiferque per Orbem &c. directs our attention to the case of Thomas Frederick Mondro Mondro, 431, New Cross road, who was fined five shillings and costs for certifying the death of a child and signing his principal's name. Mr. Mondro is the dispensing assistant of Dr. Tayler. Our correspondent asks if a qualified man has the power to sanction an unqualified man to sign a certificate of death. The answer is very simple. A qualified medical man has no such power, and in acting so would incur serious risk. It is only fair to say that the evidence showed that in this case Dr. Tayler had not given his sanction. The summons was at the instance of the Registrar-General. It is satisfactory to see the quickened interest of the Registrar-General in dealing with this great evil.

Striring.—A medical man is supposed to have the instruments mentioned. Our correspondent would do well to determine his own charges on a sober estimate of his patient's circumstances and the value of his own services. We can only suggest that for the first duty from half a guinea to a guinea would be reasonable, and for the second half a guinea. It is important that private practitioners should not charge such vaccination fees as drive their humbler patients to the public vaccinator.

Dr. Wm. Harding.—We shall be pleased to receive the paper for consideration.

ALLOXAN.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if any reader of THE LANCET can give me any information concerning a drug called "alloxan." It was discovered by Liebig, and has the reputation of being of value in cases of obstruction of bile-ducts, jaundice, &c. I am anxious to know if it has been tried, in what doses, and with what result.

I am, Sirs, yours faithfully,

Rugby, March, 1892. E. SCUDAMORE ANGOVE, L.R.C.P.Edin. &c.

THE DUBLIN CIVIL SERVICE MEDICAL AID ASSOCIATION.

Mr. J. J. Murphy.—We are obliged to Mr. Murphy for a copy of his annual report; but we hesitate to criticise it without more information than appears on the face of it. Are we to understand that the members of the Civil Service in Dublin, and, if married, their families, are attended medically for 5*s.* a year, and, if single, for 2*s.* 6*d.*? We should like more light on the social position and pecuniary means of those happy civil servants who get so much for so little. Perhaps Mr. Murphy will oblige us with a copy of the rules and other data for a judgment.

Inquirer.—We should reply in the negative.

THE PATHOLOGY OF FATIGUE.

THE Italian school has made a special study of the phenomena of fatigue, physiological and pathological. Besides the well-known treatise, "Sulla Fatica," of Professor A. Mosso, of Turin, the transactions of the several scientific bodies of Italy contain, from time to time, the results of investigations on the subject. Of such papers the two latest are those just contributed to the R. Accademia dei Lincei (the "Royal Society") of Rome. The first is that of Dr. Salvioli, entitled "Influenza della Fatica sulla Digestione Stomacale;" the second that of Dr. Albanese, on "LA Fatica negli Animali privi di Capsule Soprarrenali." (The Influence of Fatigue on Digestion in the Stomach, and Fatigue in Animals deprived of the Supra-renal Capsules.) The papers may be had in the fascicoli of the Accademia from the publishers, Messrs. Loescher, Rome, Florence, and Turin.

C. P. M. S. can claim (1) to keep fees for attendance at assizes; (2) £1 1*s.* per day and travelling expenses.

Dr. Cagney.—The announcement appeared in our last impression, p. 562.

THE HEIGHT OF ROOMS.

To the Editors of THE LANCET.

SIRS,—Your interesting article on the height of rooms intended for human habitation (THE LANCET, Feb. 27th, p. 479) tempts me to offer a mild protest against the assumption that the sanitary value of high ceilings is generally admitted. In the class of dwellings which chiefly require regulation and supervision several things in due proportion are required to secure the best sanitary results. We want a good deal of free space in relation to the total height of the building to secure light and air; we want elbow room for a family confined in many cases (here at least) to one apartment; and we want cheap rents, to leave as little inducement as possible for overcrowding. Now, it is manifest that if you insist on high ceilings you increase the height of your building, and make more dingy and airless the adjoining streets or courts. You also make the approach to the upper floors more difficult, and the building more expensive. Of course, these objections may be met by taking a storey off the height of the tenement; but how, then, about the rent, especially where ground is dear? I think there can be no doubt that the Local Government Board exercised a wise discretion in refusing to allow sanitary authorities a by-law regulating the height of dwellings; and it is greatly to be regretted if they have recently yielded to the clamour of sanitary authorities so far as to sanction by-laws prescribing a minimum height of nine feet for rooms intended for human habitation. There seems to be a growing tendency on the part of local authorities to confound things that are desirable with things that are necessary; and if the Local Government Board itself ceases to discriminate between the two, there is no saying to what lengths of extravagance local legislation may be allowed to run. Nothing can justify a Government Department in deliberately sanctioning a law which must add to the cost of the dwellings of the poor, except the proved and urgent necessity of such a law, and in the present case no such proof is possible. On the contrary, it can, I believe, be demonstrated that a ceiling a foot lower than the proposed minimum would be preferable on sanitary grounds, apart from any other, in all rooms dependent on fire flues for ventilation. I have seen no refutation of the views I advanced on this subject at the Sanitary Institute Congress of 1883 (see Transactions of the Sanitary Institute of Great Britain, vol. v., p. 204), to which I must refer, as I dare not ask more of your valuable space.

I am, Sirs, your obedient servant,

Glasgow, Feb. 29th, 1892. JOHN HONEYMAN.

*** We cannot but think that Mr. Honeyman, in enunciating principles, attaches too little importance to the fact that large floor-space with diminished height of rooms almost necessarily means crowding of floor-space at the level of the human breathing apparatus, and this especially in the case of bedrooms, together with insufficiency in cubic space. But he is in error in implying that the Local Government Board have prescribed "a minimum height of nine feet." Neither did we imply approval of such a minimum. The actual minimum referred to in the memorandum is eight feet—that is to say, just "a foot lower," such as our correspondent himself suggests.—ED. L.

ILL EFFECTS OF "THE MILK CURE."

THE *Münchener Med. Wochenschr.* publishes a lecture given by Dr. Agéron on the ill effects sometimes attending "the milk cure." The author points out that many persons have a distaste for milk, and suffer from more or less dyspepsia after taking it. This becomes a serious matter in chronic affections of the digestive organs requiring an exclusive milk diet. The symptoms in most of these cases are loss of appetite, vomiting, distension of the stomach, acid eructations, with colicky pains and constipation alternating with diarrhœa. The continuance of the treatment gives rise to general malnutrition, characterised by anæmia and loss of weight. Dr. Agéron points out that these symptoms may be mistaken for those of malignant disease. He suggests the advisability of examining the patient's digestive organs thoroughly before adopting "the milk cure," and the necessity for repeated weighings during its continuance.

Dr. Edwd. Davies.—We think a rule of the kind mentioned should not have a retrospective effect.

DR. SISLEY'S PAPER ON INFLUENZA AT THE EPIDEMIOLOGICAL SOCIETY.

AT Dr. Richard (not Robert) Sisley's request we desire to make the following corrections in the report of the meeting of the Epidemiological Society on the 17th ult. (THE LANCET, p. 581). In speaking of local outbreaks of influenza previously recorded, he referred only to the writings of Sir Peter Eade, Feissinger, and Tessier, and also said that MM. Magnin and Vaillon, at the Société de Biologie, "came to the conclusion, after careful consideration, that until French veterinarians expressed more clearly what they meant by equine influenza it was useless to draw any deductions from observations on the disease." Professor Fleming has given an exhaustive account of epizootics of influenza in his classical work on Animal Plagues, and in Dr. Creighton's recent book, "History of Epidemics in Britain," many additions have been made to our knowledge of the disease in this country. "Mr. Caird of Lochgoilhead" (THE LANCET, vol. i. 1891, p. 741)—and not "Sir J. Caird"—published an account of an outbreak in horses; whilst Ollivier's case was one in which influenza was supposed to have been communicated by a cat. As to immunity being conferred by one attack, Dr. Sisley also desires to explain that he stated the balance of evidence was that although the "protection" afforded by an attack of influenza was much less than in many other diseases, yet, *cæteris paribus*, a person who has had an attack of influenza is less likely to take the disease than one who has not had it. He suggested the possibility of some "second attacks" being akin to recurrence of malaria.

M. A. Cantab.—It is not quite certain that reference is made in the advertisement to medical practitioners.

PUSCHMANN'S "HISTORY OF MEDICAL EDUCATION."

To the Editors of THE LANCET.

SIRS,—In your review of the "History of Medical Education" in last week's issue it is stated that no allusion is made to Dr. Gilbert of Colchester in connexion with his discovery of the magnetic polarity of the globe. I beg to refer to page 350 of the translation, where it will be seen that he is referred to in this connexion. The reviewer also would substitute "Severus Alexander" for "Alexander Severus." May I be permitted to remark (1) that on the coins of this Roman Emperor the word Alexander follows immediately upon the abbreviated form of Imperator, and (2) that we have the authority of Gibbon for calling him "Alexander Severus" (*vide* "The Decline and Fall," &c., vol. i., chap. vi., pp. 204, 205; chap. viii., pp. 253, 270). Thanking you on behalf of Dr. Puschmann and on my own account for your long and sympathetic notice of the book,

I remain, Sirs, your obedient servant,

Crouch End, N., March 7th, 1892. E. H. HARE.

*** We have referred Mr. Hare's letter to our reviewer, who writes as follows:—"The meagre reference to Dr. Gilbert of Colchester certainly escaped us. But it seems to have escaped Mr. Hare also; for in his (otherwise) very complete Index Dr. Gilbert's name does not appear. As to 'Alexander Severus' for Severus Alexander, Gibbon's authority is worthless. The German Archæological Institute has discredited much of the 'Decline and Fall,' from its topography and nomenclature downwards. If Mr. Hare will consult the Cavaliere Lanciani's 'Ancient Rome in the Light of Recent Discoveries' (Macmillan and Co., 1891) he will find, *passim*, a very distinct preference for Severus Alexander. Another first-rate authority—Professor H. F. Pelham of Oxford—in his masterly digest of the History of Rome for the Encyclopædia Britannica, also gives Severus Alexander, which we therefore hope to find adopted in the next edition of the English version of Prof. Puschmann's 'History of Medical Education.'"—ED. L.

MEDICAL ETHICS AND THE LAY PRESS.

THE following two paragraphs from, respectively, the *Essex Telegraph* and the *Essex Standard* are curious. They would seem to imply prodigious skill on the part of the practitioner and the corresponding importance of the patient. That two papers should be so inspired in a matter which requires investigation by the medical man whose name is used so absurdly:—

"We are glad to learn that Mrs. Fulton, of High-street, who has been dangerously ill with congestion of the lungs following influenza, under great care and the skilful attention of Dr. Weller, is now progressing towards recovery."

"*Influenza.*—There are now comparatively few cases of influenza in Colchester. We are asked to state that Mrs. Fulton, of High-street, who has been dangerously ill with influenza and congestion of the lungs, is, under the treatment of Dr. Weller, progressing towards recovery."

"DYSMENORRHŒA."

To the Editors of THE LANCET.

SIRS,—In reply to "Baffled" I should suggest that he put his patient under an anæsthetic and make a thorough pelvic examination. It may be a case of tubercular salpingitis.—I am, Sirs, yours faithfully,

March 5th, 1892. F.R.C.S.

DIFFERENCES OF MEDICAL MEN AT HOUGHTON-LE-SPRING.

AN extract from a newspaper is sent us giving in parallel columns the opinions of two medical men delivered before a bench of magistrates on an unfortunate child, which strike the *Child's Guardian* as very contradictory. They are not so contradictory as they seem; but it is to be regretted that there should be such apparent contradiction. They are perhaps both incomplete.

Mr. Jackson (Plymouth) is thanked. The subject has been frequently discussed in our columns, and will receive further notice.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Angove, Rugby; Dr. H. Adams, Philadelphia; Messrs. Blackiston, Son, and Co., Philadelphia; Mr. Barwell, London; Messrs. Burroughs and Wellcome; Dr. Buss; Mr. Birchall, Liverpool; Messrs. Baillière et Fils, Paris; M. Belzung, Paris; M. Berthier, Paris; Mr. E. Blake, Yarmouth; Dr. Boyland, Paris; Mr. J. W. Barnes, London; Mr. E. Clarke, London; Messrs. Clarke, Wolverhampton; Mr. Cooper, Eastbourne; Dr. Charteris, Glasgow; Mr. Coleman, Cardiff; Mr. Cooper, London; Mr. Crowhurst, Hastings; Dr. J. A. Campbell, Garlands; Dr. Davies, Wrexham; Dr. W. Duncan, London; Messrs. S. Deacon and Co., London; Mr. Davis, London; Mr. T. S. Ellis, Gloucester; Mr. Elliott, South Devon; Mr. Frost, London; Messrs. Fannin and Co., Dublin; Dr. Foxwell, Birmingham; Messrs. Foster, Brown, and Co., Toronto; Mr. Ford, Devonport; Dr. B. Fenwick, London; Dr. J. Murray-Gibbes, Boost, Vic.; Dr. Guthrie, London; Messrs. Lecture
ON
SOME SPECIAL FEATURES IN THE HEART AFFECTIONS OF CHILDHOOD.

A Demonstration in connexion with the London Post graduate Course.

BY OCTAVIUS STURGES, M.D.,
PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

GENTLEMEN,—My present design is to call attention to certain features of heart disease special to children, and apt, therefore, to be overlooked or misunderstood unless separately studied. What chiefly claims notice is the nature of functional heart disturbance and of carditis in these young subjects; the frequency of recovery from such conditions; and the fact that both are often expressed by physical signs merely, the child's general health being unaffected. The latency of early heart disease in children is due in large measure to the indefiniteness of child's rheumatism. Yet not to this alone. The physical indications themselves may be difficult. This is especially the case with pericarditis. The friction graze indicative of this inflammation may be so slight or so inconstant, or so precisely synchronous with the proper heart sounds, as to escape notice. The frequency of pericarditis in connexion with slight joint pains—which are really rheumatic—is on this account much under-estimated. Until the ear is attuned to them the many modes of pericardial rubbing are hard to catch. The obvious to-and-fro friction sound of extensive pericarditis in no way resembles it. What has to be listened for is the presence of a sound or of sounds over and above the endocardial, and nearer than they are. In very many cases it is only by long and repeated listening, both with the stethoscope (varying the pressure) and with the ear applied directly to the naked chest, that this graze will be revealed, presently it may be to disappear for a while, yet once heard of perfectly definite significance. In the ten examples of heart disease exhibited here at our last meeting no less than four had pericardial graze. In all of these the rubbing had been of fugitive character, sometimes present, sometimes absent, and in none was there any open symptom on the part of the patient likely to call attention to the heart.

But with the quickest ear the frequency of pericarditis is not to be estimated by audible friction only. There may be neither rub nor graze, and yet pericarditis, of which, in that case, the earliest certain sign is effusion. Evidence of this consists in a slight shifting to the left of the apex, and a slight broadening of the cardiac triangle near its base, physical signs too small to be estimated unless the exact apex place and the exact shape of the cardiac dulness have been previously ascertained.

The recurrence from time to time in rheumatic children of pericardial friction or slight effusion, with perhaps some joint pain and tenderness, but no repetition of the original rheumatic attack and no obvious disturbance of health, is an important element in prognosis. The pericardium is as the joints; pericarditis is the equivalent of arthritis. Every recurrence of joint pains in these subjects must be regarded as a fresh menace to the heart and suggest physical examination. Yet though the discovery of a pericardial graze is no doubt disquieting, it is not easy to see what good is to be got (pain being absent) by local applications or active treatment. If we could silence the rub it does not follow that we should therewith help the heart. What does silence it sometimes of a sudden and for ever is pericardial adhesion, an event we would avoid. Children who suffer these recurrent attacks are very apt in the end to become cardiac cripples; they need extra care, with protection from exposure, mental excitement, and bodily fatigue—all in their several degrees possible provocatives of rheumatism.

Now, pericardial rubbing in the circumstances we are considering, though it may be intermittent and hard to hear, yet once heard can have but one meaning. On the other hand, what precisely are the physical signs of early endocarditis nobody knows. Where there is pericarditis, provided it is rheumatic, we may almost assume that there is endocarditis also, which may or may not presently reveal itself by infallible physical signs after the exocardial rubbing has ceased. What I would now call your attention to is the extreme caution that is necessary before pronouncing that the altered heart signs—the murmurs and disturbed rhythm which, more or less, are invariable in child's rheumatism—are of such sort as to imply heart disease. Quickened action, "excited" impulse, uneven rhythm, soft apex murmur, double second sound at mid-sternum—these are habitually concurring heart signs in acute rheumatism. As the joint inflammation subsides and the heart steadies there comes the time of doubt as to its precise physical state—a doubt which is seldom quite resolved when the patient becomes convalescent and is dismissed. The subsequent return of some of these children may decide this question in so far as they are concerned. By that time some are found to have unquestionable signs of heart disease, and some have wholly recovered. But it is obvious that the former class will return in larger proportion than the latter; so that we can never be sure whether recovery is the rule or the exception.

The first of the patients now before you, L. W——, is a girl of seven. She was admitted for acute rheumatism, of which the joint symptoms were slight, and had nearly disappeared. There was a distinct blowing murmur at the apex just after and separate from the systole, conducted about an inch towards the axilla. In a few days this murmur became fainter, and in a week it had gone. There was next (Dec. 1st) a recurrence of articular rheumatism, with some fever, pain, and swelling of the left knee and knuckle of the left hand. Recovering from this second attack in a few days, it was now noted that the heart had become unrhythmical, but there was no murmur. On Dec. 18th, when the child seemed well, a faint rubbing was heard just to the left of the sternum at the third cartilage. It became louder, but lasted only a few days. A week later (Dec. 21st) a soft systolic murmur reappeared at the apex, not constant, while the second sound in the pulmonary area became reduplicated. The last note (Feb. 4th) is to the effect that the heart is unequal in force and frequency with soft systolic murmur, ill-conducted and sometimes hardly audible.

Here is a characteristic example of heart disturbance concurring with rheumatic arthritis. The two subside together, leaving it doubtful whether or not the heart has received permanent damage. The fact that pericarditis has been heard favours the belief that there has been endocarditis also. The persistence up till now of irregular heart action, with occasional doubling of the second sound, argues on the same side. The recurrence of rheumatism suggests recurring endocarditis. But only time—some month or more, with the appearance of further and more definite physical signs, such as blowing or presystolic apex murmur, thrill, and, more than all, change in size and shape—can determine the fact that the heart is permanently crippled.

But in addition to the physical signs observed in this case, of which pericardial friction is the most distinct and significant, a presystolic murmur may come and go, and does not afford absolute proof of heart disease. We have had lately two children, neither of them known to be rheumatic, but both the subjects of marked anæmia. In the elder, a girl of seven, who has just left the hospital recovered, the extreme pallor was readily explained by repeated attacks of hæmatemesis. The spleen was enlarged, and the case resembled one of so called splenic anæmia. At first a single systolic apex murmur was heard, then a presystolic, or, as at times it might be better called, a diastolic mitral as well. And one day, when the child had been some while in hospital and was improving in all respects, a soft, double, pericardial friction sound was heard. This lasted more or less distinctly for some days during the patient's convalescence; she left the hospital free of it, and with a soft presystolic murmur only. The second and more striking example is now before you, A. R——, a boy of five. Anæmia was here extreme and quite unaccounted for. He had never had rheumatism, and there was no splenic enlargement. On the first examination of the blood (Dec. 7th), the proportion of white to red was 47 to 1; hæmoglobin 15 per cent. On the last examination (Feb. 10th), the proportion was 60 to 1: hæmoglobin 40 per cent. This child, too, on admission, had an apex systolic murmur, which afterwards became presystolic, occasional doubling of second sound, uneven rhythm, and a pericardial rub which

went and came and was at times very distinct. If you listen at this moment you will hardly perceive more than a want of strict rhythm, with a suspicion of presystolic murmur. Nevertheless the course of the physical signs, and especially the undoubted friction rub, renders it quite uncertain what the child's heart will show some months hence.

In this last case, if not in the other, the association of anæmia with pericarditis, and probably with endocarditis also, seems best explained by a common origin in the rheumatic state. Anæmia is one of the proper sequels of rheumatism. And when the most profound anæmia is otherwise unaccounted for, it may be permissible to accept the occurrence of pericarditis, notwithstanding the absence of joint pain, as confirming the rheumatic view, and thus to group and interpret symptoms either of which taken by itself is inexplicable. However that may be, the point I would now emphasise is that in these two children with presystolic murmur the physical signs of heart disorder have so far subsided that we hesitate to credit them with heart disease. We might even, I think, go so far as to say that in children there is hardly any heart action or heart murmur which, provided it be new (a provision which excludes blowing murmur, thrill, and marked presystolic or double mitral murmur), indicates for certain irrecoverable disease. Unlike what we observe in the adult, except very rarely, a slight presystolic murmur at apex, diastolic aortic murmur,[1] doubling of the second sound, equally with pericardial graze, will appear and disappear. Their significance is determined by their endurance. Time will serve in some cases to develop additional morbid signs of no doubtful meaning, and in some to restore almost or altogether the heart's natural sounds and rhythm. Acute rheumatism will always disturb the heart. That only is certain. It must be left for the future to say whether such disturbance means permanent damage.

Perhaps the best illustration of the character and course of valve murmurs in childhood—their disappearance in some cases, and in others the gradual development of obvious heart disease—is to be seen in chorea. In fatal cases of this disorder, apart altogether from rheumatism, we get, as a rule, ocular evidence of recent endocarditis which during life has given no certain sign of its presence. On the other hand, in non-fatal chorea in connexion with rheumatism we may watch week by week the gradual transition from soft mitral murmur to physical signs plainly indicative of mitral stenosis. What would be the later steps of the recent endocarditis of non-rheumatic chorea which death, and death only, reveals we cannot tell. But it will not be denied, so far as clinical evidence goes, that the mitral murmur associated with such chorea will often grow by degrees more pronounced, more blowing, and better conducted, until it becomes hard to say whether it may not be evidence sufficient of structural change. Then, and as gradually, with the recovery of the nervous disorder the heart will revert to its normal state. Putting together these facts, the anatomical and the clinical, is it too bold an inference that endocarditis is a common occurrence in chorea, that its proper physical signs are not immediately recognisable, and that the rule of it is, in this association, rheumatism being excluded, to inflict no permanent injury on the heart?

I have yet to show, by the example of a boy, J. W——, ten years and a half old, who has had recurring rheumatism, how obvious and distinct are the physical signs of formed heart disease in children. This boy, who was lately readmitted for dyspnœa fits, had at first, signs precisely similar to these others, and was regarded with the same sort of doubt. He has now, as you can easily see, enlarged heart-thrill, systolic and presystolic murmur. The hand placed on his chest at once perceives all this. The patient is a specimen of what rheumatic carditis comes to. Yet for the while these obvious heart changes are perfectly compensated. The progress of such cases follows one pattern, only the rate varies, and what chiefly accelerates it is adherence of the pericardium. Of this boy's early physical signs, when first he came under notice, one of the worst omens was pericarditis. Later he developed presystolic murmur and apex thrill, the heart enlarged, and doubt was no longer possible as to his physical state. Yet still with evident heart disease he had no dyspnœa, and was hardly different from other boys. And so he might have remained for a long time but for the occurrence of adherent pericardium.

Mitral stenosis in children, then, which is almost always rheumatic, is not at first disabling. I doubt the wisdom of making patients of these young subjects solely for the reason that their hearts are thus changed. The need for early treatment will depend very much on the recurrence or not of rheumatic attacks, and the worst event to be feared in the course of them is pericardial adhesion. Children who keep free from such attacks will go on for a long time without heart trouble. Other children less fortunate will have frequent recurrence of what is really acute rheumatism, though of short duration, with only slight pyrexia and transient joint pains. With these latter the heart deterioration in the way of dilatation is apt to be very rapid, and is indicated by dyspnœa, palpitation, and presently œdema. And there are two physical signs which as these cases progress indicate what the end is to be. One, and the earlier, is the detection from time to time with the successive rheumatic attacks of renewed pericardial friction; the other, and the later, which becomes the more obvious after the rubbing has finally ceased, is rapid enlargement of the heart area, both across and lengthways. Of the origin of this change it does not become us to speak positively in the patient's lifetime. But we know for certain, and can show you in our museum, that the common cause is adherent pericardium.

You will notice that the time usually taken in the full development of post-rheumatic valve disease exceeds the time needed for the child's full recovery from its acute symptoms. The consequence is that in most instances it is only by the accident of a second admission that we get to know the sequel of carditis, whether in permanent damage or gradual recovery. Sometimes, however, as in the child I now show you, the changes are so rapid that we may follow them step by step, almost day by day; and during the short period of a single admission note the transition from abnormal cardiac signs which are changeful and indeterminate to those that afford conclusive evidence of organic disease. The patient in question (L. P——) is nine years and a half old, and on admission had recently had rheumatism. Without entering into particulars of her case, except to say that she gradually improved in general health, it will serve my present purpose to quote a few short entries from the notes referring to the heart signs:—"Jan. 7th (on admission): The apex between the fifth and sixth spaces in the nipple line. Cardiac dulness not enlarged; no thrill. At the apex a soft systolic murmur conducted into the axilla and faintly heard at the angle of the scapula. There is a friction-like rub at the apex, and also to the left of the sternum in the third and fourth spaces.—14th (a week later): The systolic murmur is rather more blowing. Just above the apex and to the left of the sternum is now a second murmur occurring early in the diastolic period, there being a short interval between the second sound and murmur.—19th (twelve days later): The diastolic murmur is only faintly heard. There is now slight rubbing at both apex and base.—21st (fourteen days later): Murmur at apex is blowing. Internal to nipple and along left edge of sternum, after the second sound, is a murmur which, in some revolutions, assumes rather the character of reduplication of the second.—Feb. 3rd (twenty-seven days later): No diastolic murmur is heard, but internal to nipple after the second sound a short sharp bruit not occupying the whole of diastole.—Feb. 8th (thirty-two days later): The bruit noted on Feb. 3rd after second sound has gradually faded, the systolic apex murmur is well heard behind at angle of scapula.—23rd (forty-seven days later): Cardiac dulness now extends to a finger's breadth outside left nipple. The systolic apex murmur is blowing and prolonged and conducted to back. It is immediately followed (or interrupted) by a sharp second sound, succeeding which is a post-diastolic murmur. At the base there is now double aortic murmur, the second sound is audible only over pulmonary area. There is marked thrill." These extracts, taken in their sequence, are characteristic of the mode in which indeterminate physical signs are gradually exchanged for those that are more definite. Systolic apex murmur of very doubtful significance becomes more prolonged and blowing; there comes presently an additional murmur in the diastolic period; friction rub is heard. But at the first none of these signs are constant, and the opinion as to organic disease formed one week may be questioned

[1] Though no example was exhibited at the time of this lecture, I make no doubt that a regurgitant aortic murmur occurring in the course of acute rheumatism may disappear within a short time of its inception, leaving out of account cases where it is difficult to distinguish endocardial murmur from pericardial rub.

Digitized by Google

the next. Yet, on the whole, the more significant and ill-omened physical signs become more obvious and more persistent, and at last the occurrence of thrill, marked presystolic murmur, and sometimes, as in this instance, signs of aortic disease besides, with perceptible increase in the heart's size, complete the evidence in favour of permanent and extensive lesion. Meanwhile the patient himself is gradually regaining his former health, disturbed by the rheumatic attack, and by the time heart disease is established beyond a doubt he is apparently well.

That is one and a too common ending of acute rheumatism in children as regards the heart. There is also another. Let me, in conclusion, contrast this patient with one just returned from the convalescent home at Highgate. A. C——, aged seven, was shown to you at the last meeting, and had then signs similar to those of L. W——, just mentioned—namely, pericardial rub, reduplicated second sound, alternating with presystolic murmur. On Jan. 15th the note is: "Systolic murmur at apex, soft and blowing and conducted well into axilla; heard also at angle of scapula. To the right, and a little above left nipple, is a loud presystolic murmur. At the second and third spaces, near sternum, friction rub is heard, increased in loudness on pressure." There seemed at this time little to choose between the children as regards their future prospects of heart disease. But now, on careful examination of the two side by side (Feb. 26th), L. W. shows the indubitable signs of extensive heart disease just mentioned, while A. C. has a rhythmical heart, without murmur or any physical signs whatever portending mischief to come.[2] The points which have been discussed and illustrated may be thus stated:—1. Heart disease in childhood, whether functional or organic, is apt to be overlooked and misunderstood. Overlooked because its early signs are often only discoverable by careful physical examination, and misunderstood because such divergence from the normal as in the adult usually implies structure change is in the child often due to temporary disturbance. 2. Owing to the equivocal symptoms of acute rheumatism in children and the indistinct and intermittent character of pericardial rub at that age, the occurrence of pericarditis, which may mean the commencement of heart disease, often escapes notice. 3. The earliest physical signs proper to endocarditis cannot be defined. The heart's sounds and action are invariably modified in acute rheumatism, and while pericarditis almost implies endocarditis, irregular rhythm, systolic apex murmur, doubling of second sound, slight presystolic murmur, will all in their several degrees suggest it; but indubitable signs of material heart change are gradually developed as the result, and not by the mere presence, of endocarditis. 4. The clinical history and morbid anatomy of chorea warrant the belief that mitral systolic murmur, increasing until it becomes slightly blowing, and then decreasing until it disappears, may be due to a form of mitral endocarditis common in chorea, less common in rheumatism, that is recovered from without heart deformity. 5. Mitral stenosis, the common sequel of rheumatic endocarditis, is not at once disabling. The well-being of a child having this defect depends largely on his immunity from subsequent rheumatic attacks, however slight; and what chiefly abridges the period of health he will enjoy is the occurrence of adherent pericardium either in the first or some later attack.

[2] This final examination was made at a ward visit three weeks after the lecture. It is here appended in further confirmation of the text.

REMUNERATION FOR EXTRA MEDICAL SERVICES DURING THE INFLUENZA EPIDEMIC.—The Farnham Board of Guardians have awarded the following sums to their district medical officers for extra services rendered necessary by the recent influenza epidemic. To Messrs. Tanner, Sloman, and Gibson, £10 each, Mr. Manders (Frimley) £6, and Mr. Whiting (Shottermill) £4.

ROYAL LONDON OPHTHALMIC HOSPITAL.—During the past year 1892 in-patients and 25,553 out-patients were treated, and 2126 operations were performed. There was a falling off in the year's income, arising from a decrease in the amount of legacies. The expenditure was £6333, which the committee deemed absolutely necessary to provide for the reception and care of the patients. Additional support was urgent. With reference to the new building, which is to cost £35,000, it was hoped the money would soon be subscribed.

ABSTRACT OF THE

Milroy Lectures

ON THE

PHYSICAL AND MENTAL CONDITION OF SCHOOL CHILDREN.

Delivered at the Royal College of Physicians, London, March 8th, 10th, 15th, and 17th,

BY FRANCIS WARNER, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE II.

THE SIGNS OBSERVED IN DESCRIBING CHILDREN.

"CRANIAL ABNORMALITIES appear to be the most important defects in development; they are the most numerous and have the highest pathological correlation of any sign with 'abnormal nerve signs,' 'low nutrition,' and 'mental dulness.' Boys, 1528; girls, 1048—total, 2576. The size and probable volume of the brain are points of first-class importance, and the size of the cranium is in children a fair indication of the size of the brain. The following standard of the normal in a well-developed child of good potentiality may be given: head circumference at nine months 17·5 in., at twelve months 19 in., at seven years 20 in. to 21 in. This, I believe, to be a high-class standard of the normal, too high if deviations therefrom are to be considered as pathological; after three years of age 19 in. cranial circumference is too small. The figures given indicate the number of cases in which the condition stated was noted among the 50,000 children seen in this inquiry. Boys, 26,884; girls, 23,143. Defects of the cranium may be divided into subclasses. Small heads: Boys, 327; girls, 738—total, 1065. It is seen that in this group, contrary to the usual rule, the defect is more common among girls. If there be no other defect, mental faculty may be average, but the child usually remains thin and delicate. Such cases in after life may undertake good work and do it, but are more liable than others to exhaustion, migraine, and break-down of the nerve system. At school these children are often delicate and irregular in attendance from ailments. Large heads: Boys, 257; girls, 46—total, 303. It seems probable that a large proportion of these cases resulted from rickets at an earlier period, for of the 168 cases of rachitis with defect of cranium, 55·3 per cent. were large heads. Cranial bosses: Boys, 495; girls, 129—total, 624. Cranial bosses are most usual at the site of the ossific centres of the two halves of the frontal bone; they may occur at the sides of the head over the parietal centres and elsewhere, as well as at the site of the anterior fontanelle. Asymmetrical heads: Boys, 84; girls, 16. These did not appear to have marked correlations with defects. [Various other defects of head and forehead were then described.] The palate was ill shapen in 1331 children, standing next to the cranium both in frequency and in a high correlation to defectiveness; the palate was examined in all children. The frequency of the various types has been given, but their relative correlation was not determined; there were twenty-two cases of cleft palate in the 50,000 children. The ears were malproportioned in 1047 boys and 268 girls. [The various forms of defect were described. Among pathological curiosities supernumerary ears, remnants of branchial clefts, congenital absence of ear, &c., were described; the adherent lobe did not appear as a marked defect.] The epicanthis was noted in 898 children. It appeared to have a lower correlation with defectiveness than other signs; when associated with defects of the cranium, however (90 cases), the defectiveness of the group of cases was very marked. Defective growth in the bridge of the nose (455 cases) did not appear to be associated with rickets; the condition appears to be outgrown in many children, and its pathological correlation is not high. Among conditions of the facial tissues notice was taken of cases of 'features large and coarse, 251'; 'palpebral fissures small, 181'; 'mouth small, 44'; 'bridge of nose in its soft tissue redundant, 61.' It is important to note each feature separately, as the defects seem to have different correlative values. The epicanthis was found to a considerable extent local or endemic in certain districts. These defects are often

Digitized by Google

associated. A hairy forehead, large frontal veins, and a small face under a well-made calvaria were found in some cases. Prognathous type was noted in eleven boys, ichthyosis in seventeen cases, congenital cyanosis in three boys; there were various other minor defects."

Passing on to the description of "abnormal nerve signs," Dr. Warner proceeded to enumerate them, the number found among the 50,000 children, and to give their pathological correlations.

"Expression defective: Boys, 694; girls, 474. This sign has the highest pathological correlation of any nerve sign. The term is here used to connote the general expression of the face, as above and apart from the special muscular balances and action described further on; a good expression may be present with abnormal coarse muscular action. Frontal muscles overacting: Boys, 1322; girls, 1616. Horizontal creases are thus formed; these muscles may often be seen working in athetoid fashion under the skin. The sign may appear in children at any age, and is usually most marked when they are least occupied. Corrugation: Boys, 199; girls, 40. This knitting of the eyebrows may be a 'coarse' or a 'fine' movement; like the last sign, it may be athetoid in character, and the two signs often coexist. Orbicularis oculi relaxed: Boys, 522; girls, 343 The skin of the lower eyelid is relaxed, puffy, and bags forward. The sign often accompanies fatigue and recurrent headaches. Eye movements defective: Boys, 798; girls, 485 The eyes may wander and fix badly, or they may be too immobile, so that the child follows a moving object by turning the head, not by moving the eyes. Nearly half of these children were dull at lessons. Two modes of hand balance were described. In the weak type—715 boys, 504 girls—the wrist and digits fall into moderate flexion; the 'nervous type'—550 boys, 516 girls—presents flexion of the wrist with over-extension of the digits. The former type is common in weak children, the latter in those who are irritable, nervous, over-mobile. The percentage correlations are for the 'weak hand' defects in development 47, low nutrition 18, mental dulness 38; for the 'nervous hand' defects in development 43, low nutrition 25, mental dulness 33. Finger twitches: Boys, 445; girls, 261. This condition, though more common in boys, passes on to chorea more frequently in girls. Lordosis: Boys, 184; girls, 279. The lumbar spine is markedly arched forward when the hands are held out in these cases. Head balance asymmetrical: Boys, 219; girls, 319. The percentage correlation of this sign is high; defect in development 61, low nutrition 29, dull 45. Among the less frequent abnormal nerve-signs were described 'general defective balance,' 'defective response in action,' 'speech defective,' 'mouth open,' 'grinning,' 'nystagmus,' 'ptosis,' 'tremor'; these minor groups included 668 children."

REMARKS ON PNEUMONIA AS A CAUSE OF DEATH IN ASYLUMS:

WITH AN ACCOUNT OF A SERIES OF CASES WHICH OCCURRED IN THE CARLISLE ASYLUM IN 1888.

BY J. A. CAMPBELL, M.D., F.R.S.E.,
MEDICAL SUPERINTENDENT, COUNTIES ASYLUM, CARLISLE.

THE average death-rate from pneumonia taken for a period of five years from the Registrar-General's returns for England is 6·1 per cent. of the total deaths. Pneumonia in 1890 caused 7·1 per cent. of the total deaths, but this year is probably an exceptional one from the prevalence of influenza and sequent pneumonia. An average of five years should, and probably does, give a fair idea of the proportion in which pneumonia stands to other causes of death. Considering the care which is expended on lunatics in public asylums, at the first glance one would say it was unlikely that the average percentage of deaths from pneumonia would be as high in asylums as the total of returns show it in England. For my own part, until I looked into the matter I was ignorant on the subject, as I have never seen it touched on in any medical book or paper. If the Commissioners in Lunacy were to adopt the table of the Psychological Association, giving the causes of death and the age at death, it would add greatly to the value of their returns. Had it been in use I could easily have ascertained the proportion of deaths from pneumonia in asylums. The Scotch commissioners in their table of deaths adopt a classification based on the Psychological Association table; but as they group all pulmonary diseases except phthisis it is valueless for any inquiry into a special lung disease with that exception. Now that post-mortem examinations are the rule in asylums it would be of great advantage if the lunacy boards in England and Scotland would introduce into their reports death tables drawn up in such form as to give the information contained in the table of deaths of most asylum reports, and the Irish Lunacy Board would do well to begin life anew with their fresh inspectors, and issue a series of tables; which would be of some value, unlike those hitherto in use.

As I was unable to get, as one should, the information from one source, I set about collecting statistics to give me a fair average of the death-rate of pneumonia in asylums in the following manner. I took the total deaths for 1890 in ten Scotch asylums, in twenty-six English county asylums, and in eight English borough asylums; they numbered 3065, while the deaths from pneumonia numbered 250 (8·1 per cent.). I took the total deaths for 1889 in ten Scotch asylums, twenty-seven English county asylums, and ten English borough asylums: they numbered 3607, while the deaths from pneumonia numbered 194 (5·3 per cent.). I also took the total deaths and deaths from pneumonia during 1887 in twelve Scotch asylums, thirty English county asylums, and eight English borough asylums. The total deaths numbered 3402—220 deaths from pneumonia, or 6·4 per cent. of the total deaths. As there seemed a considerable disparity in the percentage of deaths in these years I pursued the inquiry further. I took a ten years' period of seventeen asylums and worked out the individual percentages of the deaths from pneumonia in each instance. I give the table here, as it may be of use, perhaps, even to the medical officers of some of the asylums where the death-rate from pneumonia is high; they may be able to ascertain some special cause, and guard against it in the future:—

TABLE I.

Showing the total Deaths and Deaths from Pneumonia, with Percentages for Ten Years ending 1890, in Seventeen Asylums.

Name of asylum.	Total deaths.	Total deaths from pneumonia.	Percentage of deaths from pneumonia.
Hants	932	15	1·6
Beds, Herts, and Hunts	934	41	4·3
Stafford	915	44	5·2
Leicester	448	35	7·8
Glamorgan	762	53	6·9
Abergavenny	604	47	7·7
Beverly	260	6	2·3
Chester	641	42	6·5
Rainhill	1054	68	6·4
Lancaster	1469	122	8·3
Whittingham	1415	117	8·2
Carlisle	490	30	6·3
Newcastle	285	29	10·1
Northumberland	341	38	11·1
Edinburgh Royal	765	39	5·0
Glasgow Royal	334	23	6·8
Fife and Kinross	279	24	8·6
Totals	11,932	777	6·5

A glance at this will show the vast disparity which exists in the cause of death by one disease in different asylums; and geographical position doubtless accounts for it. I know few asylums situated in more cold localities than the Newcastle and Morpeth asylums, and there the death-rate from pneumonia is singularly high, while it is extraordinarily low at Hants. I do not see why it should be so high at Whittingham and Lancaster. I think it will be quite conceded by all that exposure to cold is one of the most common causes of pneumonia, although no doubt other causes, some of which at present we are ignorant of, contribute in the production of this disease. I then massed the total deaths of the three years and the totals of the seventeen asylums. They amounted to 22,006, of which 1441 were from pneumonia—a percentage of 6·5. This, considering the large number of deaths taken, should be a fair percentage. It is 0·5 above the death-rate for five years from pneumonia in England, and it points strongly to the conclusion that as a cause of death pneumonia figures too highly in asylums, and it might be well for all who have to do with insane patients to look if possible into the causes of their pneumonias. When I deal with the period of the year at which pneumonia is most rife, I shall have only my own experience

Digitized by Google

to go on, as I cannot without vast trouble to others get such information. Is pneumonia caused by exposure in cold weather in working parties of dements of feeble circulation who frequently are allowed to sit thinking of nothing when they should be on the move? Do patients after a warm bath on bathing nights go to bed as they should in all asylums, or in some do they go from the warm bath to their usual avocations? I analysed the deaths from pneumonia in the ten asylums, and found that in seven instances the deaths were proportionately higher among the men than the women; and on taking the total of these ten asylums I found the male deaths from pneumonia preponderated. This is also the case at Garlands. It is what one would expect, for as a rule, even in asylums, men are more exposed from out-door occupations to the climatic causes which give rise to this disease. Outbreaks of pneumonia have not been unknown in asylums, as one may perceive from asylum death tables. When they occur the superintendent should allude to them in his report, and where possible give his solution of their cause, if he does not report them in a medical paper, for whatever can throw more light on this subject is desirable from a scientific point of view. In the report for 1887 of the Montrose Asylum, Dr. Howden fully reports a series of cases which occurred there in March and April of 1887; eleven cases of pneumonia, two of pleuro-pneumonia, one of bronchitis, and one of pleurisy during March; and one of pleurisy, two of pneumonia, and one of pleuro-pneumonia during April; also twenty-one cases of acute lung disease, with twelve deaths, between March 20th and April 16th. He gives the mean temperature during March and April, which was low, and says, "There can be little doubt, however, that the sudden cold, added to some unknown condition, was an important factor in the production of lung disease." The following sentence occurs in the report of one of the Visiting Commissioners, dated July, 1886: "It must be recognised, in spite of so much that is gratifying in the condition of the asylum, that it is still more crowded than it ought to be." Is this the "unknown condition" mentioned by Dr. Howden? I believe vitiated air proves a very important factor in the causation of pneumonia—or, more correctly speaking, the transition from vitiated air to cold. Many people can tell with accuracy that their attack was originated by coming out into the cold air from a crowded meeting or close church; and not long ago two well-known members of Parliament took pneumonia, which proved very rapidly fatal, from walking home on a cold night from a crowded house. During the thirty years the Carlisle Asylum has been opened only 41 deaths from pneumonia have occurred—3 8 per cent. of the total deaths. During the first fifteen years of its existence only nine deaths occurred from this cause—7 men and 2 women (2 6 per cent. of the total deaths). During the fifteen years ending 1891 32 deaths, 19 men and 13 women (4·2 per cent.). In Table I. the Carlisle percentage of deaths from pneumonia is shown for the ten years ending 1890 as 6·3, but this rate is greatly caused by the results of one year, and it is the outbreak of this year that I now propose to deal with. I show in Table II. the number who died, as well as the number who were under treatment for pneumonia at the Carlisle Asylum during fifteen years ending 1891:—

TABLE II.

Showing Deaths from Pneumonia and those under Treatment for Fifteen Years ending 1891.

Year.	Deaths from pneumonia.			Under treatment for pneumonia.		
	Male.	Female.	Total.	Male.	Female.	Total.
1877	0	0	0	0	1	1
1878	0	0	0	0	1	1
1879	1	0	1	4	1	5
1880	0	1	1	3	1	4
1881	2	1	3	7	4	11
1882	1	0	1	1	3	4
1883	2	3	5	2	6	8
1884	2	3	5	9	6	15
1885	3	0	3	4	1	5
1886	0	1	1	2	2	4
1887	0	1	1	2	1	3
1888	7	1	8	14	5	19
1889	1	1	2	4	2	6
1890	0	0	0	2	0	2
1891	0	1	1	0	2	2
15 Years' Totals	19	13	32	54	36	90

An examination of this table will show that more men were affected by pneumonia, and also died of it, than women, and that an unusual proportion of deaths took place from it in 1888, and an unusual number of patients were affected by it. Fourteen of the nineteen who were affected by the disease were so between April 22nd and July 24th. Now, June and July are not common months to see pneumonia in at all. In ordinary experience one sets down pneumonia as occurring most in January, February, March, and April. I worked out all my cases for fifteen years, and, excluding this exceptional year, I found them stand thus: In January, 9; February, 5; March, 13; April, 11; May, 6; June, 3; July, 1; August, 2; September, 5; October, 3; November, 7; December, 5. In March and April they were most frequent, and next January and November. I think most practitioners will bear me out when I say that this is very much what is seen in practice outside of asylums.

TABLE III.

Direction of wind the day before and day of onset, with dates.	Showing portions of lung affected, with result.
1888.	
Jan. 7th, W.; 8th, S.W.	T. F., male, 71 years; epileptic dementia. Death after 7 days. Posterior portions of right lung in a state of red hepatisation.
March 7th, S.W.; 8th, S.E.	E. T., female, 70 years; melancholia. Death after 7 days. Upper lobes of right lung in a state of red hepatisation.
March 11th.	J. B., male, aged 35; mania. Left base affected. Recovered. Came in with pneumonia present.
April 21st, N.E.; 22nd, N.E.	M. E. J., female, 35 years; dementia. Base of left lung affected. Recovered.
April 30th, S.E.; May 1st, S.S.E.	T. B., male, aged 48; general paralytic. Right lung affected. Death after 6 days. Upper lobes of right lung in a state of red hepatisation.
May 11th, S.; 12th, calm; 13th, W.	G. G, male, aged 53; dementia. Right base affected. Recovered.
May 16th, S.E.; 17th, S.; 18th, S.E.; 19th, S.E.; 20th, W.S.W.; 21st, S.W.	J. B., female, aged 40; mania. Both bases affected. Recovered.
June 5th, S.E.; 6th, S.E.	G. M., male, aged 34; dementia. *Left* lung affected. Death in 6 days. Left lung throughout in a state of grey hepatisation.
June 6th, S.E.	J. F., male, aged 42; mania. Left base affected. Recovered.
June 7th, S.E.	J. G., male, aged 68; melancholia. *Left* lung affected. Died in 5 days. *Left* lung almost entirely solid, passing from red to grey hepatisation.
June 12th, S.E.; 13th, S.	T. H., male, aged 64; mania. Died in 6 days. Whole of left lung and base of right lung in a state of grey hepatisation.
June 19th, N.N.W.; 20th, N.E.	T. H., male, aged 38; dementia. Died in 5 days. Upper portions of right lung in a state of red, lower of grey hepatisation. Base of *left* lung in a state of grey hepatisation.
June 26th, calm; 27th, S.E.	M. N. W., male, aged 49; dementia. Both bases affected. Recovered.
June 28th, calm.	Bd. S., male, aged 54; mania. Right base affected. Recovered.
June 29th, calm.	R. R., male, aged 57; dementia. Died in 5 days. Upper portion of right lung in a state of red, lower in a state of grey hepatisation, and base of left lung in a state of grey hepatisation.
June 30th, N.E.; July 1st, N.E.; 2nd, S.S.E.; 3rd, W.; 4th, W.	P. L., male, aged 40; dementia. Left base affected. Recovered.
July 18th, E.; 19th, E.; 20th, E.; 21st, S.; 22nd, S.E.; 23rd, S.; 24th, calm.	S. T., male, aged 48; mania. Died in 6 days. Right lung throughout in a state of red hepatisation, also base of left lung.
Nov. 5th, E.; 6th, S.E.	B. M., female, aged 26; imbecile. Base of left lung affected. Recovered.
Nov. 10th, S.E.; 11th, S.S.E.	J. O. C., female, aged 75; dementia. Base of right lung affected. Recovered.

I now deal with the outbreak of pneumonia which occurred at Garlands Asylum. Table III. shows the number of patients who had pneumonia and who died of it in 1888, with the date of onset of disease, and the direction of the wind on that day and the day before. I at first attributed this outbreak to the east wind, which that year was more persistent than usual; but I subsequently came to the conclusion that another factor might, and probably did, play an important part in originating the disease. In dealing with this outbreak I exclude the cases which occurred in January, March, and November. They, I believe, were due to ordinary climatic causes. One of the patients got a chill by being brought from her ward to see her clergyman, as it was getting dark on a cold night in March, with a bitter east wind blowing. She complained almost at once, and next morning had the physical signs of pneumonia. The old farmstead of Garlands, with piggeries attached—which had existed from time immemorial, and since the opening of the asylum had been fully inhabited, containing usually from seventy to a hundred pigs, besides horses and cows—was pulled down, and its foundations rooted up, between the middle of April and the end of July, 1888. The farmstead was situated due east of the centre main door of the asylum, at sixty-six yards' distance from it, but it was within twenty yards of a portion of the men's ward, where eighty men lived. The construction of the total asylum is such that any wind, except west, might blow floating rotten débris from the in-course-of-being-razed steading into some portion of the asylum, and where buildings project swirls of wind often are seen to be diverted, and carry floating objects even in directions which the usual course of the wind would not but for artificial obstruction. Now,[1] from April 21st to July 24th inclusive, ninety-four days, wind west, or with west in it, only blew thirty days. Calm days only amounted to nine; on the other fifty-five days the wind blew on some portion of the buildings from this steading. The mean temperature for May was 0·01° above the usual average, but for June it was 1·6° below it, and 2·7° for July. The mean temperature for May was 48·5°, for June 52·8°, for July 53·8°. Of the fourteen patients who had pneumonia between April 21st and July 24th 12 were males, 2 females, and of the 12 males 8 were employed in demolishing the old buildings, 3 lived in the most contiguous building to the work, and the other lived in a building opposite to it. I am aware that it may be said, If you think the floating débris was the primary cause of this outbreak, why did it not affect more of the people engaged at work? and how was it that none of the attendants were implicated? It is exceedingly rare that an outbreak of any disease attacks all who are in its vicinity. Some individuals are less susceptible to diseases than others. As a rule, people who work with dusty material do so on the wind side. Many of those who were at work might have had the sense to do this, and though close to the source of evil have been all the safer from this proximity. It is usually dements of low circulation, depressed nerve condition, and generally low vitality, who in asylums suffer first, and most seriously, from deleterious surroundings or exposures. I strongly suspect, and I think with reasonable grounds, that the razing of this old and foul building, which never should have been permitted to exist in such propinquity to the asylum, had an intimate relation to the outbreak of pneumonia I record. Though I am aware that one, if not more, recorded outbreaks of pneumonia have been ascribed to similar causes as this I mention, I purposely abstain from attempting to quote references on the subject, as my not having easy access to a medical library would prevent my doing so exhaustively.

I believe congestion of the lungs, which otherwise might go on to pneumonia, may be arrested by prompt treatment. The following was a well-marked case: A. H——, aged fifty-five, an M.R.C.S., told me on the morning of Dec 19th, 1886, that he had a rigor the previous night, and that he believed he was in for pneumonia. He had the signs of acute congestion of one lung. Temperature 103°; pulse 114 I gave him a bath of from 110° to 114°, put him to bed with much extra covering, made him swallow a stiff tumblerful of hot toddy and a good dose of Dover's powder, and put a large mustard poultice on his chest. He perspired profusely. His temperature quickly fell, but rose at night to 102·4°, but next day was normal, and he seemed well. I adopted the same treatment in several cases with success, and in a good many without success. In cases of very high temperature in pneumonia I have used antipyrin. I do not consider the treatment by forced reduction of temperature conducive to recovery. Pleuritic effusion is not often seen in this asylum. Aspiration has only twice been required in the last fifteen years: once in the case of an attendant whose chest had subsequently to be drained for empyema sequent to influenza; the other occasion, a patient whose one side of chest was full, containing 75 oz.; he was a stupid dement. His illness was not noticed at first. That pleuritic effusions are not common in most asylums is probably owing to early treatment and warmth.

I think I am warranted in summing up the contents of the foregoing as follows:—(1) That the percentage of deaths from pneumonia is higher in asylums than among the general public, and in asylums the male sex are most liable to it; (2) that this should not be the case, considering the amount of care and money which are expended on lunatics; (3) that the geographical position of some asylums, with the accompanying lowering of temperature, accounts for a high percentage of pneumonia in them; (4) that a high death-rate from pneumonia seems to occur in some asylums which are not situated in cold regions, and that inquiry should be made into the causes; (5) that various causes predispose to and originate pneumonia, and where exceptional outbreaks appear thorough investigation should be made, probable causes should be ascertained, and the matter should be carefully recorded; (6) that an exceptional outbreak of pneumonia took place at the Carlisle Asylum during April, May, June, and July, 1888; (7) that the period of the year at which this outbreak took place pointed to some special or exceptional cause, as January, February, and March are the most usual months to see pneumonia in; (8) that this outbreak chiefly affected the male patients, and was synchronous with the razing of an old farmstead which was contiguous to the male division; (9) that eight of the patients affected were employed at work in demolishing the buildings, and three resided in the buildings next the work, and the wind blew from such directions during the period of the attack as to justify the belief that inhaled débris might be the principal factor in the production of the disease; (10) that the number of cases of pneumonia at Carlisle Asylum is usually not high year by year, the percentage of deaths from it to other causes being only 3·8 over a period of thirty years,—this, almost more than any other circumstance, points to a special and exceptional cause for the outbreak.

Carlisle.

[1] For the direction of the wind and mean temperature I have to thank T. G. Benn, Esq., of Newton Reigny Observatory, who always most kindly puts his observations at my disposal for such purposes as this.

A SUCCESSFUL CASE OF LAPAROTOMY FOR A SUPPURATING HYDATID CYST OF THE LIVER.

BY ALEX. G. R. FOULERTON, L.R.C.P.LOND., M.R.C.S.

IN this paper it is proposed to give some short notes about a case of suppurating hydatid cyst of the liver on which I lately operated. The patient, Michael B——, aged fifty-five, came under my care in St. Bartholomew's Hospital at Chatham, on July 18th of last year, having then been in the hospital three days. He had been a soldier; ten years of his foreign service had been passed in Malta and Gibraltar, and the last twelve months in Bermuda, just sixteen years ago. He described himself as having been a healthy man, and up to quite lately had been subject to no illness worth speaking of. But about two months ago he began to feel unwell. During these two months he had been constantly conscious of some slight tenderness on pressure over the right hepatic region. Three weeks before admission his skin suddenly became yellow, and at the same time his urine was of a dark-brown colour. This attack of jaundice seems to have been transient, lasting but four days. When I first saw the man his general appearance was good; no sign of jaundice was noticeable. He had really nothing much to complain of except the slight tenderness already mentioned, and a certain feeling of lassitude and weakness. His principal excretions were

natural. The upper margin of liver dulness was normal as to its level; the lower margin descended lower than usual, reaching in the middle line to just above the umbilicus. Towards the left the region of dulness extended as far out as the nipple line. Neither the margin of the liver nor any definite tumour could be marked out by palpation. The subcutaneous veins of the right side of the chest below the nipple were considerably engorged. The earlier readings of the temperature chart were as follows:—

	Morning.	Evening.		Morning.	Evening.
July 15th ...	97·6°	99·6°	July 19th ...	98·0°	98·4°
,, 16th ...	97·4°	100·6°	,, 20th ...	98·4°	98·8°
,, 17th ...	97·4°	98·4°	,, 21st ...	98·2°	99·0°
,, 18th ...	97·4°	98·4°	,, 22nd ...	98·4°	99·2°

Then, on the morning of July 23rd, it was seen that a considerable fulness had developed, and it seemed quite suddenly, in the epigastric region. The lower margin of this swelling, which was obvious to the touch, corresponded fairly accurately with the lower margin of dulness already mapped out by percussion. The recti muscles moved freely over the surface of the swelling which was clearly not adherent to the abdominal walls, rising and falling with respiration. The pulsation of the aorta was transmitted very distinctly through the tumour, in which no bruit could be heard or any expansile pulsation detected. The swelling gave a certain sense of elasticity to the touch, but definite fluctuation was not to be obtained. During the next week nothing was done. The man remained in excellent condition; his only complaint was against confinement to his bed. The swelling increased very slightly, if at all, in bulk. The temperature was somewhat irregular.

	Morning.	Evening.		Morning.	Evening.
July 23rd ...	98·0°	100·4°	July 27th ...	97·8°	100·0°
,, 24th ...	98·8°	98·0°	,, 28th ...	98·0°	99·2°
,, 25th ...	98·4°	98·6°	,, 29th ...	98·0°	100·6°
,, 26th ...	98·6°	100·0°	,, 30th ...	98·6°	99·4°

On July 30th the patient did not feel quite so well as he hitherto had felt. He had occasional pain, described as griping, in the region occupied by the swelling. His tongue was coated, and he was inclined to vomit.

July 31st: Patient remained in much the same condition. In the evening he had a rigor, followed by profuse sweating. Morning temperature 98·4°, evening 100·4°. — Aug. 1st: The man was better again, the feeling of nausea had left him. Morning temperature 98·4°, evening 101·6°. — 2nd: Condition of things remained unaltered. An exploring syringe introduced into the more prominent part of the swelling and in the middle line struck pus at a depth of about two inches. Morning temperature 98°, evening 99·8°.—3rd: Chloroform having been administered I made an incision about three inches and a half in length along the middle line, the ends of the wound being at an equal distance from the sterno-xiphoid joint and the umbilicus respectively. The peritoneum having been reached, was opened by an incision of similar length. The surface of the liver, natural in appearance, presented at the opening; it was free from any adhesion to the abdominal wall. The lower margin of the liver was examined by the finger, and the gall-bladder felt slightly distended, but the surface presented by the gland was so much increased that a thorough examination was impossible with an opening of the size made. Three or four exploratory punctures with a hollow needle from the middle line towards the right proved unsatisfactory. But the first puncture towards the left reached pus. Some attempt was now made to attach the liver to the margin of the peritoneal wound by sutures. But this attempt, as might perhaps have been foreseen, resulted in failure, the sutures cutting through the gland and its capsule very readily. The liver was then steadied as much as possible by external pressure, and a pair of dressing forceps were thrust into its substance along the hollow needle, as a guide. As some pus oozed up the blades of the forceps were separated and quickly withdrawn. A rent, about two inches long, in the liver substance was the result, and through this there was a large gush of sweet thickish pus, containing numerous daughter cysts. Whilst the forceps were being withdrawn the two forefingers were passed into the pus-containing cavity, and thus the margins of the opening in the liver were hooked close to the abdominal walls. The flow of pus having ceased, it was ascertained that the opening led through rather more than half an inch of liver substance into a cavity, the walls of which, so far as they could be explored, were lined with soft gelatinous material. Five deep sutures of stout silk were then passed by means of a large strongly-curved needle from within the cyst through the liver and overlying abdominal walls. These being firmly tied shut out the peritoneal cavity effectually, leaving a gaping wound which readily admitted two fingers and led directly into the cyst cavity. These sutures, it may be mentioned, did not appear to cut through the liver substance as the superficial ones had done, probably because the cyst wall below and the abdominal wall above presented a sufficient resistance to their cutting action. The interior of the cyst wall, wherever it could be reached, was rapidly scraped with the finger-nail and washed out repeatedly with warm water. When this water returned quite clear about a drachm of iodoform was introduced into the cavity and a pad of absorbent wool applied over the wound. The patient, after the evacuation of the large volume of pus, had become collapsed in the extreme, but rallied quickly when he was put back into bed. Morning temperature 99°, evening 99·6°.—4th: The patient had passed a good night and was comfortable in the morning. The pad having become soaked with sweet blood-stained discharge the wound was dressed. The cavity of the cyst had contracted considerably and its walls could be examined everywhere with the finger introduced through the wound. The walls were also becoming everted at the margins of the opening. The cyst was washed out with tincture of iodine and warm water (half an ounce to the pint), a small quantity of iodoform introduced, and a fresh pad of the absorbent wool applied. Morning temperature 98·6°, evening 99°.—5th: The patient was doing very well; the amount of discharge on dressings was much less. The cyst was washed out and treated as before. Morning temperature 99°, evening 99·4°.—6th: Morning temperature 98·8°. The patient was doing well in every way. Very slight amount of discharge. The continued eversion of the cyst had produced a granular mass around the opening. Wound dressed as before.

On this last date I left Chatham, and cannot give any detailed notes of the further progress of the case. I have since learned, however, that this progress was satisfactory. The sutures were removed, and the patient ordered up on August 11th. Recovery was uninterrupted, save that the patient suffered from a typical attack of ague one afternoon when he was up and about. He had not suffered from ague before, so this attack was probably incidental to his stay in the hospital, which is situated in a distinctly malarial district where such attacks are common enough. The wound had healed up, and the man appeared to be quite cured when he left the hospital shortly afterwards. The case has been reported because operations for suppurating hydatid disease are not of very frequent occurrence in this country, and when they do occur the termination is not always satisfactory. But after the bare notes have been given there is not much more to be said in the way of comment. The cyst must have been connected with the under-surface of the left lobe of the liver, which was more or less flattened out on its surface. Its size was doubtless considerable, judging by the large quantity of pus which escaped. The rapidity of its contraction and subsequent spontaneous eversion must be attributed chiefly to the normal intra-abdominal pressure and the presence of an opening of fair size. Eversion at the time of operation, a procedure which has sometimes been recommended, was not judged to be expedient, partly because of its seeming difficulty in this particular case, partly because of the collapsed condition of the patient. And if it had been performed I do not think that the cure would have been better or more rapidly accomplished. From the wounded liver substance there was little or no haemorrhage. Why this was I am unable to say. From what one has seen of other wounds of this organ the opposite might have been anticipated. More than half an inch of the gland substance was penetrated, but the tissue might possibly have been rendered less vascular by the pressure to which it had previously been subjected. The sudden swelling which appeared at the epigastrium on July 23rd, caused either by some sudden alteration of the position of the cyst, or by some sudden increase in its size, is also difficult of exact explanation.

ON A FORM OF PAINFUL TOE.

BY L. G. GUTHRIE, M.B. OXON., M.R.C.P. LOND.,
PHYSICIAN TO REGENT'S-PARK HOSPITAL FOR EPILEPSY AND PARALYSIS, ASSISTANT PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL, AND TO THE CHILDREN'S HOSPITAL, PADDINGTON-GREEN.

THE intense suffering caused by this complaint, and the prompt and certain relief which may be obtained by suitable yet simple treatment, lead me to record my own experience of a special form of painful toe. Both in symptoms and pathology the complaint is identical with that to which Dr. Auguste Pollosson, in 1889,[1] gave the name "anterior metatarsalgia." Only in the latter the metatarso-phalangeal joints are affected, whilst in the former the distal phalangeal joints are alone involved. In order to avoid a more cumbrous designation I have called the former affection "a form of painful toe." In either case, under the influence of prolonged standing or walking in tight boots, the ligaments of one or more joints, metatarso-phalangeal or phalangeal only, become strained, slight subluxation takes place, the nerves are stretched and pressed upon by the partially dislocated bones, and the characteristic pain is produced. The pain occurs suddenly, and with a sense of something giving way at the site of the joint affected. It is relieved by taking off the boot and gently pressing the displaced bones into proper position. The reduction is always accompanied by a sharp twinge of pain, followed by instantaneous relief. I have only met with one case of the major affection. It was that of a tramcar conductor, who suddenly developed the symptoms, and had suffered from them for three months. The pain was under the head of the third metatarsal bone, and he could relieve it by taking off his boot, flexing his toes whilst pressing gently with his finger on the site of the pain. His occupation prevented him from carrying out this treatment as often as he desired, so I directed him to wear a boot with a very broad sole, slightly convex on the upper surface, so as to support the sunken head of the third metatarsal bone, and with plenty of room across the base of all the toes. This treatment proved thoroughly satisfactory. The following are cases of the minor but similar affection—painful toe.

CASE 1.—In the autumn of 1883, after a long day on duty as hospital dresser, I walked through the wet streets to the opera. The theatre was crowded, and I had to stand throughout the performance. Towards the close I suddenly felt most severe shooting and burning pain in the fourth toe of my left foot. The boring of a hot iron into the flesh might have caused similar pain. It extended up the nerves of the outer side of the foot and leg into the sciatic, with a numbing, sickening sensation. I limped home, with dismal misgivings lest I had fallen a premature victim to gout; but on taking off my boot I discovered that the last phalanx of the fourth toe was over-extended, whilst the head of the second phalanx was slightly displaced downwards. Reduction caused a sharp twinge of pain, followed by immediate relief. From this time for many months I was constantly liable to these attacks of pain, especially in hot, damp days, after standing or walking for any length of time. I learned to reduce the dislocation and obtain relief by treading heavily on the empty part of the toe of my left boot with the heel of my right, and then forcibly drawing the left foot back within the boot, at the same time elevating the toes against the "uppers." Both the displacement and the reduction were accompanied by a distinct click. This manœuvre became necessary with more and more frequency, and the pain increased in severity until I had serious thoughts of having the toe amputated or the joint resected. At last, with the happy inspiration of Mark Twain's hero, who after twenty years' confinement opened his cell door and walked out, I discovered an equally easy means of escape. My boot, though quite comfortable when first put on, became too tight across the toes as soon as the foot became at all congested. Under this condition the last phalanges became jammed and fixed together, whilst the relaxed ligaments of the second joint of the fourth toe allowed the head of the second phalanx to drop and press painfully upon the nerves. I ordered a boot with plenty of room for lateral expansion of the toes, and I was at once freed from the attacks of pain which made my life a burden.

CASE 2.—A gentleman recently consulted me on what he believed to be a soft corn between the fourth and little toe of the right foot. On examination I could find no trace of the soft corn, but infantile paralysis had left his foot with slight talipes varus and marked pes cavus. The great toe was hyper-extended and pointed outwards at an acute angle from the metatarsal joint. The rest of the toes were crushed together in the form of a cone; the fourth toe was laterally flexed, and almost hidden beneath the third. The calf muscles were wasted, and the limb was nearly three-quarters of an inch shorter than the other. To counteract the shortening he had worn for many years an extra three-quarter-inch heel inside his boot. The sole was not similarly raised, so he was compelled to walk in a downward plane, forcing his toes together at each step into his somewhat pointed and short boot. He suffered no inconvenience from these deformities until the beginning of the year 1891, when he acquired the habit of walking on the outside of his foot, bearing especially on the outer side of the little toe, in order to avoid resting his full weight on the ball of the great toe, which was unduly prominent and tender. In July, 1891, during a long walk, he was suddenly attacked by acute pain in the little toe. The sensation, he said, was as if a hot fusee were placed between his toes, and were burning slowly outwards through the little toe. From that time until I saw him three months later, he had been constantly subject to these attacks of excruciating pain, and they had so increased in frequency and severity that he said he would have his toe amputated at once if he could not otherwise obtain speedy relief. He could wear a loose slipper with comfort, but on walking in a boot for even a few yards the pain occurred. It was not relieved by taking off the boot, but he showed me how, on gently pressing the tip of the little toe outwards, the pain instantaneously ceased, the manœuvre being accompanied by an extra sharp twinge of pain. Obviously his suffering was due to slight inward displacement of the last phalanx of his little toe, and consequent stretching and compression of the nerves between the displaced bone and the adjoining toe. The treatment in this case was not so simple as in my own, owing to the various deformities of his foot. But to make the story short, complete relief was obtained by a boot contrived on the following principles: Plenty of room was given across the toes, the little toe being especially relieved of all pressure. The outer side of the fore part of the sole was raised, and the heel lowered, so as to throw his weight from the outer to the inner side of the boot, and to prevent forcing of the toes together. A graduated depression was made beneath the ball of the great toe, in order to avoid walking on the downwardly displaced head of his first metatarsal bone.

Remarks.—These cases form additional links in the chain of evils attendant on wearing boots too tight across the toes. Patients will be probably loth to admit that a form of boot to which they have always been accustomed, and which they have regarded as both comfortable and elegant, can be the cause of their sudden attacks of pain. And the latter they will readily attribute to gout or rheumatism; for to the non-professional public, pain in a toe means gout, and pain elsewhere in a limb means rheumatism. Not only do the paroxysms of pain strongly resemble those of gout, but it is possible that the strained and unnatural position into which many force their great toes may account for the prevalence with which those parts become the primary seat of true gout.

Upper George-street, Bryanston-square, W.

ACUTE OTITIS; CEREBRAL ABSCESS; OPERATION, AND DEATH.

BY W. K. HATCH, M.B.,
SURGEON-MAJOR, BOMBAY ARMY.

THE following case, terminating in cerebral abscess, was under the observation of a careful practitioner from its commencement up to its termination by death after operation. The patient, a man aged twenty-seven years, resided in rather a low-lying part of Bombay, and was in fair circumstances. Up to the present illness he had enjoyed good health. He was attacked by acute inflammation of the right

Digitized by Google

ear on March 19th, 1890, followed a week later by similar inflammation of the left. Both drums were much congested, and severe pain, with deafness, was complained of. Ultimately rupture of both membranes took place; and when I first saw him, on April 25th, there was a large perforation in each, with considerable congestion of the drums and meatus; there was a very profuse discharge from both ears, and a good deal of deafness. By May 23rd the discharge had entirely ceased, and soon afterwards hearing on the left side became normal, but the patient continued to be very deaf in the right ear; the perforations had completely healed, and the appearance of both tympanic membranes was nearly normal; some congestion, however, remained present. Curiously enough, the patient's wife on April 27th of the same year was also attacked by acute inflammation of both ears, which ended by perforation and discharge of pus. Subsequently the discharge stopped, and hearing was perfectly restored. No further symptoms were noticed up to July 20th in the husband, he having meanwhile returned to his work in an office and being apparently in good health, although he had certainly lost flesh and colour since his illness. He now began to complain of neuralgic pains about the right half of the head, particularly in the supra-orbital region and the side of the neck. The pains continued for about ten days, and then slowly disappeared; the left side of the head was then affected in a similar manner. About the middle of August the pains on the right side reappeared, but could not be in any way localised; the neck was said to be painful but not at all tender. Tonics were given and anodyne applications to the head and neck were used; they gave temporary relief. Being suspicious of the formation of an abscess we carefully examined the patient, but nothing definite except loss of flesh could be made out. On Sept. 5th, for the first time, the pain was said to be more confined to the back of the head, somewhere about the posterior inferior angle of the right parietal bone. The paroxysms of pain came on at various times during the twenty-four hours, and were very severe in character, necessitating the frequent injection of morphia, which had a very good temporary effect; if not immediately injected the patient became wretched in the extreme, begging for the morphia, and quite unable to bear the sharp pain which he felt shooting down the neck and back of the head. On Sept. 10th we again saw the patient, and I felt convinced that there was an abscess somewhere in the brain, but could not localise it. There was and had been no fever, but the severe pain, inability of the patient to do any work, and the fact that he seemed rather stupid and slow in answering, were very suspicious symptoms. As the patient was of a sallow complexion naturally, it was difficult to say whether there was or was not any change in his appearance. The pulse was feeble and slow, and he suffered from dyspeptic symptoms, constipation, and loss of flesh. The eyes were normal. I accordingly recommended an exploratory operation, but the relatives would not hear of it. The patient continued in this state, suffering severe pain and becoming almost frantic and uncontrollable if not at once injected with morphia, so that his medical attendant was constantly being sent for both night and day. On Sept. 18th the patient became delirious and remained so until the 20th, when I again saw him, with Brigade Surgeon W. Gray, who agreed with me that immediate operation was necessary. Arrangements were completed for its performance that day, when, a little before the appointed hour, the patient became suddenly conscious and intelligent; the relatives, therefore, would not permit the operation to be performed. He now stated that he felt pain behind the right ear and tenderness on percussion over the temporal bone. The severe neck pains still, however, continued. There was no paralysis of any muscles discoverable, and the appearance of the membrana tympani was unaltered. Next day we succeeded in getting the consent of his relatives to an operation, and chloroform was administered. It was then believed that the muscles of the left arm and leg were much sooner under the influence of the anæsthetic than those of the right side, which remained rigid until there was complete anæsthesia. A small flap was then dissected up behind the right ear, and a small trephine applied an inch and a quarter above and behind the meatus; a trocar was then slowly introduced, and after it had gone into the brain about three-quarters of an inch a quantity of healthy-looking pus escaped, to the amount of an ounce and a half. A drainage-tube was put in and dressings applied, and the patient awoke free from pain. Next day he rapidly became unconscious, and died about noon. No examination was allowed. In this case acute otitis was followed by cerebral abscess very rapidly, and ended fatally within the year. No cause could be ascertained for the ear attack, either in the case of the man or his wife.

I am indebted to Mr. Shepherd, who attended him, for part of the notes in this interesting case.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

DEATH BY AN ELECTRIC SHOCK.

BY WALTER BUCHANAN, M.R.C.S., L.S.A.

ON March 4th I received a message to visit an accident by an electric light alternating current of 2400 volts. The patient was seen by me, as far as I could judge, about ten minutes after the accident; he then presented the following appearances. The face was livid, lips congested, pupils dilated, bloody mucus issued from both nares, his hands were almost clenched. He was lying on his back, inclined a little towards the *right side*. *Artificial respiration* was resorted to, he inspired slightly three times, and then died. In about four minutes he became quite rigid. There were no marks of violence on the body or head, but on the palm of the right hand there was a dirty mark (no doubt that of japan) about three inches by half an inch. There is no doubt now that this was fused off an iron bar, which it was proved he had in his hand, by the electric current, he having struck at the induction wire off which the insulating indiarubber was fusing. After having raised the bar to strike at the wire, he fell back with *one cry* for help. He was then carried away insensible to the place where I visited him.

Thirty-one hours after death, in conjunction with Drs. Voisey, Holroyde, and Burns, I made a post-mortem examination, and the following appearances were noted. The deceased appeared to be about the age of twenty-six; he was 5 ft. 8 in. high, and weighed about 11 st. The body was well-nourished and strongly muscular; it was cold, post-mortem rigidity well marked, no marks of violence, lividity well marked. Incision showed a quarter of an inch of fat. Abdomen looked healthy when first opened; on lifting up the great omentum the superficial intestines were slightly congested, and the deeper intestinal contents highly congested (hyperstatic). Kidneys normal in size, capsules not adherent, but deeply congested. Liver firmly and universally adherent on the upper surface, normal in size, and very deeply congested. Gall-bladder normal, containing two drachms of fluid. Urinary bladder congested, containing two ounces of fluid. Spleen firmly adherent to the posterior part by bands of adhesions, slightly enlarged, and deeply congested. Stomach contained much semi-digested food and some evidences of old inflammation. Heart normal in size, superficial veins highly congested, right auricle distended, right ventricle flaccid, left ventricle firm and solid, left auricle empty; blood liquid from one to two ounces; walls normal in thickness, no hypertrophy or dilatation; aortic and pulmonary valves slightly thickened and nodular; cordæ tendineæ normal; right auriculo-ventricular ring admits three fingers, and the left one two. Lungs: Right one firmly and universally adherent; both universally congested, the right one more than the left. Tarry blood and air issued on pressure; lungs float easily in water; entire absence of disease. Epiglottis: Larynx and trachea deeply congested, but otherwise normal; no foreign body in larynx. Brain healthy, but congested. Spinal cord healthy, but congested.

Remarks.—We particularly noticed the tarry condition of the blood, as it has been stated that this is caused by the action of the electric current on the red blood-corpuscles. The auriculo-ventricular rings were no doubt enlarged by muscular contraction. The cause of death was evidently by asphyxia. The case is interesting, as we get very limited evidence of deaths from electricity. In those occurring from lightning coroners rarely engage the services

Digitized by Google

of medical men, and far more rarely order a post-mortem examination, taking other evidence for granted. I cannot conclude without thanking the medical men before mentioned for their valuable coöperation and assistance.

FATAL CASE OF INHALATION OF ROBURITE FUMES.

By W. A. HATTON, M.B.

IT is a strange coincidence that while a committee was investigating the probable effects of this explosive compound, of which THE LANCET of last week gave so able a summary, a fatal case should have occurred lately in the Atherton district, the leading features of which will, no doubt, be of interest on account of its very rare occurrence. The deceased, a miner, was at work on Feb. 9th, and allowing a reasonable time (eight minutes) to elapse after the firing of a roburite shot, proceeded to take down the hanging coal. Ten minutes afterwards he complained of pain in the head and faintness, though he worked till closing time. The next day, when I saw him, he was in a confused condition and complained of a good deal of dizziness and pain, chiefly above the frontal and supra-orbital region; his articulation was thick and almost unintelligible; he was, however, able to give a short account of the whole occurrence, and attributed the onset of the symptoms to the inhalation of the fumes. There were some nystagmus and indistinctness of vision, owing no doubt to the retinal congestion present. The pulse was thready and irregular, ranging from 70 to 90 in the minute; temperature 101°; there was also marked cyanosis about the lips. The respiration was good, though a little hurried, and there were no abnormal physical signs on examination of the chest, no cough or odour noticeable in the breath, neither was there anything to lead to a suspicion of any pulmonary congestion. There had been no vomiting or feeling of sickness. The knee-jerk was a little exaggerated. The cephalalgia became more intense, coma rapidly supervened, and the patient died on the third day. The post-mortem examination was made, in conjunction with Dr. R. Martin of Atherton, on the 15th; the only noticeable point on external examination was the cyanosis of the lips. On opening the skull the dura mater was adherent, and found to be inflamed; there was intense venous congestion on the brain surface, and there was some superficial encephalitis present. Punctiform ecchymoses were unusually numerous on section, and very little fluid was present in the lateral ventricles. On opening the thorax, there was no odour perceptible, as has been noticed in cases of nitro-benzine poisoning; the lungs were intensely congested, more so at the apices, though there was no sign of any inflammatory change. The remaining organs were quite healthy, and portions of lung, liver, the stomach, and a kidney were sent to Dr. Paul for especial examination, though with negative results. There was no trace of carbon monoxide in the blood, tested by the spectroscope, or of the presence of any nitro-benzine compounds. In the report drawn up by Professor Dixon and Messrs. Mounsey and Hannah in the Park-lane Colliery dispute, in relation to the probable effects of the use of roburite, the presence and smell of nitro-benzine were detected in the fumes. On the other hand, at a meeting of the Manchester Geological Society the fumes were stated to be nothing but carbon dioxide and nitrogen; and the joint commission appointed by the workers and owners of the Durham collieries declared that there was no trace of nitro-benzine found in their experiments.

Walkden.

INTER-PARTUM HOUR-GLASS CONTRACTION.

By H. MARTYN EAMES, L.R.C.P. & S.ED., L.F.P.S.GLAS.

THE following case of inter-partum hour glass contraction seems to me to be of sufficient rarity and interest to warrant its publication.

On Sunday, Jan. 31st, I was called to a young multiparous woman in labour, whom I had delivered with forceps eleven months previously. On examination I found the os uteri fully dilated, and the uterine contractions strong and regular. I therefore ruptured the membranes, which resulted in the rapid descent of the head to the perineum. After this the pains gradually, as in her last labour, became inefficient and unsatisfactory; so I applied the forceps, and her delivery was effected without any difficulty, and in about a quarter of an hour a placenta was expelled. Having discovered it to be a case of twins, I examined for the purpose of ascertaining the presentation of the other child, when I found that the liquor amnii had escaped, and the left arm was presenting. I therefore determined, if practicable, to turn and deliver without delay; but upon introducing my hand into the uterus I found the internal os uteri intensely constricted, rigidly unyielding, and tenaciously gripping the upper region of the presenting arm, rendering it impossible for me to pass even one finger beyond the barrier into the upper uterine segment. There being no special indication on the part of the mother for immediate delivery, I determined to await the effect of forty grains of chloral hydrate in two doses of half an hour's interval. On re-examination I found that the internal os had slightly relaxed, and that the funis had descended, and was being compressed by the contracted ring, the pulsation being only slightly appreciable. However, I was able to return the prolapsed cord, but fœtal turning was out of the question, as I was unable to pass more than a couple of fingers through the constriction. In the interests of the child, as indicated by the almost pulseless cord, I placed the patient deeply under chloroform for the purpose of prompt delivery, by turning if possible. Despite this the obstruction only yielded very slightly, and as I found the funis had ceased to pulsate, and there being no maternal indications for immediate delivery, I decided to leave matters alone for a while. In an hour or so I was summoned to my patient, when I found the contraction obliterated, uterine action regular and efficient, the arm obtruding from the vagina and the shoulder had descended into the pelvis. I again administered chloroform, turned and completed the delivery without any further trouble. The hand and arm of the child were deeply cyanosed, much swollen, and a deep sulcus remained on the upper arm at the point where it was gripped, thus proving the intensity and persistency of the spasm. I have referred to several authorities, who only describe cases of ante- and post-partum hour-glass contraction, and hence I presume that hour-glass contraction after the birth of the first child in cases of twins is of very rare occurrence, and it suggests itself to me that it may not be inaccurately defined as *inter*-partum hour-glass contraction.

ST. BARTHOLOMEW'S HOSPITAL.

ACUTE YELLOW ATROPHY OF LIVER; NECROPSY.

(Under the care of Sir DYCE DUCKWORTH.)

THIS case is recorded as it appears worthy of notice, first, on account of the rarity of the disease, and, secondly, because it differs in some respects from most other published cases. As in many older cases, the jaundice followed a mental shock. With the onset of coma physical signs pointed to rapid diminution in the size of the liver. This probably cannot wholly be accounted for by the shrinking of the liver, but must be partly due to some change of its position—falling away from the ribs. Instead of the urine, as was supposed usually to be the case, being not very deeply bile-stained, albuminous, and with diminution of salts and urea, the excretion in this case was exceedingly deeply bile-stained, not albuminous, and contained a fair amount of salts and urea. The urea, however, in this case was only estimated by the nitrogen method, which, like Liebig's method, is open to error. The nearly complete absence of any hæmorrhage throughout the case is noteworthy. For the account

Digitized by Google

of this case we are indebted to Mr. F. P. Weber, house physician.

E. S——, aged forty-one, a fish-curer, was admitted into the Elizabeth ward on Oct. 23rd, 1891. History (gathered from her relatives): The patient was in her usual health up to Sept. 26th, 1891. On that date she is said to have received a great mental shock from seeing her youngest child nearly run over in the street. On the following day the patient vomited several times, and jaundice commenced. She did not complain of any abdominal pain at this time or just before. The yellow colour of the skin has gradually deepened since then, and vomiting has continued on and off. Menstruation was regular up to the commencement of the jaundice. Since then she has "lost blood" on and off. No epistaxis or hæmatemesis. During the last fourteen days she has complained much of pain in the left hypochondriac region. She is said to have been "queer in her head" for the last three days, constantly yawning, confused in her ideas, asking funny questions, and doing apparently purposeless things. There was negative history as regards the possibility of phosphorus poisoning. The patient is said to have been always temperate in alcoholic drink, and to have enjoyed good health usually. Never any mental illness. Never jaundice before. There was no history of syphilis. One of her sisters is insane.

On admission the patient was very drowsy, and lay quietly in her bed. At very short intervals she yawned with considerable noise. She sometimes answered questions addressed to her correctly, but often repeated answers to a former question several times, apparently not knowing that a new question had been asked. Temperature subnormal. Respiration natural; pulse rather infrequent. She was exceedingly deeply and brightly jaundiced, the greenish-yellow colour of the skin contrasting strikingly with the flushed and dilated veins on her cheeks. Tongue clean. Pupils equal; ophthalmoscopic appearance of eyes natural. No discharge from the ears. Nothing abnormal was found in the heart or the lungs. The liver dulness commenced at the sixth rib; the edge was felt just above the level of the umbilicus in the nipple line. Spleen not felt; no tenderness to pressure. Very slight lumbar œdema. The upper limbs are moved naturally; no rigidity. Lower extremities were rigidly crossed. Knee-jerks excessive; much ankle clonus on both sides.

Oct. 24th.—Mental condition much worse; will not answer questions. Constantly giving noisy yawns. Seems to see nothing. Recurrent utterances of "Oh, my!" "Oh, dear!" "Oh, my!" "Oh, dear!" at short intervals, with yawns interspersed. Pulse 72; regular, rather excessive tension. Eyelids drooping. Edge of liver not felt. Can draw up the legs. Bowels confined. Urine passed unconsciously, about a pint in the night; sp. gr. 1012; no albumen or sugar; fairly dark with bile pigments.

25th.—Very little sleep last night, in spite of the hypodermic injection of $\frac{1}{15}$ grain of the hydriodide of hyoscin. This morning she is in a deep sleep, a semi-comatose condition, and has to be fed by nasal tube; liver edge not felt; lower limbs not so rigid; knee-jerks excessive, and marked ankle-clonus as before; no plantar reflex; sensation very dulled; the patient just feels the prick of a pin. Urine: sp. gr. 1012, neutral, deeply coloured with bile pigment; no albumen; under the microscope crystals of tyrosin are seen and deeply bile-stained bodies (?leucin); urea estimated 1·6 per cent. The tyrosin crystals increased in number on letting the urine stand till next day. Bowels not opened by two calomel and colocynth pills; small hard white scybala came away after a soap enema.

26th.—At 12.45 A.M. deep coma; respiration 60; pulse 120, very great tension; temperature rising. Eyes: nothing abnormal seen by ophthalmoscope. Liver: no dulness in back or axillary region; one inch and a half of liver dulness in front in the right nipple line from the sixth rib downwards; urine passed into bed, but eight ounces saved. The respiration gradually became shallower, and the patient died at 5.50 A.M.

The temperature was below 98° until the evening of Oct. 25th.

25th Oct., 11 P.M., 100·6°.	26th Oct., 3 A.M., 101·0°.
26th ,, 1 A.M., 100·4°.	,, ,, 4 A.M., 102·0°.
,, ,, 2 A.M., 100·6°.	,, ,, 5 A.M., 102·6°.

Examination of the last eight ounces of urine: It was dark-brown coloured, turbid, the turbidity slightly clearing upon boiling; alkaline; not a trace of albumen. Chlorides, sulphates, and phosphates, about the natural amount. Urea, 1·5 per cent. Two ounces concentrated failed to show leucin; a similar amount concentrated failed to show tyrosin. Examination by microscope of the sediment: It seemed to consist of amorphous phosphates and of "rods" and "crossed-stick" crystals of phosphate of lime. No crystals like tyrosin were seen, even on carefully neutralising the urine and saving it up. The treatment consisted in feeding the patient when she refused food, and relieving the constipation. The presence of tyrosin crystals in the urine decided the diagnosis.

The post-mortem examination was made on Oct. 27th, thirty-one hours after death. Examination of the head and neck was not permitted. Considerable subcutaneous fat; rigor mortis in legs, not in arms; brightly jaundiced; no eruption; congestion of dependent parts; lungs emphysematous, congestion of dependent portions; heart flabby, no valvular disease; some atheroma of aorta and vessels. Abdomen: Liver, weight twenty-eight ounces, completely hidden under the ribs, adhesion to hepatic flexure of colon; the gall-bladder contained some thin yellowish fluid, which could be pressed out through the papilla of the duct. Liver is uniformly small, with soft wrinkled capsule; easily indented by a small stream of water from the tap. The liver substance is everywhere mottled, tracts of a yellowish colour being interspersed amongst tracts of a deep reddish tissue. By microscope: Liver cells were quite broken up in most parts; at other spots they were still to be recognised, though looking shrivelled and angular; around the portal vessels everywhere was a dense infiltration of small round cells; no crystals could be seen in freshly cut sections. The spleen weighed five ounces, soft and decomposing. Pancreas soft. Lymphatics and suprarenals natural. Kidneys natural size; capsule separated easily; cortex a little thin in places. Under the microscope there appeared to be a little increase in the interstitial fibrous substance.

CHISLEHURST, SIDCUP, AND CRAY VALLEY COTTAGE HOSPITAL.

COMPLETE EXCISION OF THE RIGHT ELBOW-JOINT TWICE WITHIN SEVEN MONTHS; RESULT.

(Under the care of Mr. GEO. WM. DAVIS.)

THE points of especial interest in this case are—(1) The absence of pus in conjunction with well-marked caries; (2) symptoms simulating the onset of tubercular meningitis; and (3) the fact of there being but one inch of shortening after the removal of three inches from the continuity of the bones of the limb.

H. M——, aged nine, first came under notice on April 10th, 1891, and was admitted into the hospital on the 16th. The patient, a clever, pleasant-looking lad, markedly emaciated about the body, but showing no signs of disease save in the right elbow-joint, which had been flexed for two years, with loss of all movement and disused on account of pain. No family history of tubercle. On admission the right arm was markedly atrophied; the right elbow, half an inch larger than its fellow, was wanting in distinctive shape and felt relatively hot; of the landmarks about the joint only the condyles could be defined; pressure over the coronoid process caused pain.

From April 16th to May 12th every local treatment was resorted to which it was thought might improve the condition, with cod-liver oil as medicine. No improvement having taken place, it was resolved to excise the joint. On May 13th, assisted by other of the medical officers of the hospital, Mr. Davis performed the operation as follows:—The patient being under chloroform, the usual single incision over the back of the elbow was made, and the inner and outer flaps carefully dissected up by short strokes of the knife, the cutting edge being continually towards the bone; the extreme softness of the olecranon process caused some difficulty. The flaps being cleared from the condyles the olecranon process was removed by an oblique saw cut. The joint was now easily opened, and much diseased synovial membrane was removed by scraping and dissection, as were also pulpy granulations filling the olecranon fossa. The forearm now being flexed to its fullest extent, it was possible to force the head of the radius and extremity of ulna through the incision. One-eighth of an inch was sawn from the articular surface of the ulna, the cartilage had disappeared, and the surface was

Digitized by Google

hard and roughened beneath the section; the bone appeared healthy and resistant. The head of the radius was now removed for a quarter of an inch, leaving the orbicular ligament intact. On the under surface of the section removed an elliptical yellow patch was observed, suggestive of tubercle; beneath this patch in the shaft of the radius was a cavity of tubular form, a quarter of an inch wide and three-quarters of an inch long, extending towards the tubercle of the radius. The cavity was bounded by hard bone, and contained matter which resembled broken-down sequestrum, but nothing suggestive of pus. This cavity was carefully scraped. The articular cartilage of the humerus was eroded, so the end of the bone was removed up to the condyles, half an inch externally and three-quarters of an inch internally. The whole of the surfaces exposed by the operation were then irrigated by means of a syphon douche, the fluid used being half an ounce of carbolic acid, half an ounce of tincture of iodine, and two ounces of glycerine to one quart of water at 105° F. A drainage-tube was inserted and the incision brought together by eight sutures. The arm was then fixed on an interrupted splint in an almost extended position and dressed with iodoform, protective pine-wool bags, jaconet, and carbolic gauze bandages. The operation had taken two hours and a half. The after-progress of the case was highly satisfactory so far as recovery from the operation was concerned. The patient was out of doors on May 31st. The first passive movements were commenced on June 1st, but were at this time and every other attended with pain. On June 20th the patient was sent to St. Leonards for three weeks. On his return on Aug. 11th no marked improvement had occurred; the condition was almost identical with that before the operation. On Aug. 19th an attempt was made to improve the movement under chloroform.

From Aug. 23rd to Sept. 30th alarming symptoms developed. Unaccountable vomiting, the temperature became intermittent (from Sept. 2nd to the 15th it never fell below 100 F., and on two occasions reached 102°), night screaming, constipation, retention of urine, sweating of the head, and nystagmus were noted. The eyes were examined by direct method, and revealed signs representing optic neuritis. The right elbow had improved in contour, and was free from pain. On Oct. 25th Mr. J. B. Lawford kindly saw the patient, and reported: "Oct. 25th, 1891: Eyes examined ophthalmoscopically: pupils atropised; refraction hypermetropic, about 2 D; exact measurement not recorded; media clear. Optic disc in each eye hyperæmic; margins blurred, and showing radial striation (visible nerve-fibre bundles); vessels at the upper and lower edges partially obscured; no measurable swelling; no hæmorrhage or exudation; vessels not kinked. These appearances most marked in the left eye. The vision was not tested, but was said to be good. The appearances were thought to be due to the hypermetropic refraction, and not indicative of neuritis from intracranial mischief." In confirmation of the above favourable opinion of Mr. Lawford, the boy was found to be gaining weight. On Sept. 4th he weighed 43 lb., and this gradually increased until on Oct. 24th, when he weighed 49 lb. A second operation was therefore contemplated, and on Nov. 23rd, 1891, the right elbow was re-excised, Dr. Battiscombe again giving his assistance. All the stages of the operation were conducted as on the first occasion, but the incision was internal to that of May 13th. The bones removed in this operation were the end of the humerus, part of the ulna and of the radius. There was no definite disease observable; the bones were rough and coated by what had the appearance of organised inflammatory exudation; there was a firm fibrous band uniting the radius and ulna, and the head of the radius was filled with fibrous material. The extent of bone removed was nearly one inch from the humerus, three-quarters of an inch from the radius, and one inch from the ulna. The dressing of the limb was the same as on the previous occasion. There was so much oozing after the operation as to necessitate a fresh dressing; perhaps this may have been due to the bloodless method of operating. The arm was redressed on Dec. 1st, 4th, and 7th. The temperature never rose beyond 99°. On Dec. 16th, the incision being united and firm, the splint was removed, and passive motion to a considerable extent was practised without causing any pain. Passive motion and massage were practised for twenty minutes twice each day until Jan. 20th, 1892, when there were then some pain and stiffness, but these completely disappeared after one week's complete rest of the arm in a sling. At the date of this report—that is, eleven weeks after the operation—the boy can touch his right ear with his right little finger; he can put his hand to his mouth, he can hang from a horizontal bar, can take coal from a scuttle by means of a shovel and place the coal on the fire, an exercise which requires some strength and variety of movement on the part of the arm used.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Adjourned Debate on Phagocytosis and Immunity.

AN ordinary meeting of this Society was held on March 15th, the President, Sir George Humphry, in the chair.

The discussion on Phagocytosis and Immunity was resumed by Dr. RUFFER, who said that he accepted Metchnikoff's view in its entirety. Not one-half of those who had spoken had defined what they meant by immunity. It meant freedom or exemption, and in its absolute sense it was almost an impossibility; for there was no animal naturally protected, or artificially so, that could not be killed by micro-organisms if a sufficient number were introduced. "Resistant" was a word he preferred as better than immune. Metchnikoff had been accused of saying that the destruction of micro-organisms was effected entirely by amœboid cells, but he had never gone so far as that. Dr. Woodhead had already stated what we knew for certain of the origin of amœboid cells; he himself had not stated that all amœboid cells were derived from leucocytes, but he had simply asserted that he had seen such a thing happen. In some of the invertebrates the actual process of development could be watched. As for the ingestion of the micro-organisms by the cells, all that was needed was a lens, a little frog's lymph, and some anthrax bacilli, and the process could then be easily watched. Dr. Klein had laid especial stress on the fact that the process was sometimes reversed, and he instanced leprosy and tubercle as examples of it; but even in these cases the destruction of bacilli was always more marked than the destruction of cells. His experiment of injecting bacilli into the lymph sac of a frog was a fallacious one, for far too great a quantity was introduced, and though the leucocytes of a frog might comfortably be able to destroy as many bacilli as would kill a mouse, yet they could not annihilate as many as would kill an elephant. Dr. Walker and he had injected into adult guinea-pigs a small quantity of a pure cultivation of bacillus pyocyaneus, and the destruction of the micro-organisms introduced was so well performed by the amœboid cells that not a single bacillus penetrated into the viscera of the animal. But if at the time of the injection of the organisms into the guinea-pig a small quantity of chloral was injected into the other side, the leucocytes would be paralysed, and the animal would die with all its organs absolutely crammed with bacilli. There was no evidence to show that the fluids of animals which had been chloralised were better or worse cultivating media than those of animals which had not been chloralised. The poison of the micro-organisms might cause the attraction of the amœboid cells, while under other conditions the poison might repel the leucocytes. If a small piece of sponge soaked in pure turpentine were placed under the skin of a frog, after a time no leucocytes would be found accumulated round it; but if the sponge were soaked with turpentine diluted with olive oil, in a short time it would be found to be crammed with leucocytes; it was evident from this that turpentine would act differently according to its state of concentration. He then proceeded to criticise Dr. Klein's rival theory that the bacilli were attracted by the cells. The argument that the bacilli were found in the cells simply because they preferred to go there was, he thought, absurd. If a lamb were found inside a dead lion it did not follow from that that the lamb of its own choice took refuge there. While he admitted the excellence of the work done by Buchner, he could not agree with that worker that the fluids of a living animal played any part in killing bacilli, and he proceeded to quote much evidence against this view. It was a most remarkable fact that if the serum of an animal was found to possess the power of killing any germ, yet that same microbe, if injected into the living tissues of that animal,

Digitized by Google

would flourish and multiply. Indeed, the only exception he knew to this was the white rat, which was not only resistant against anthrax, but its serum was also bactericidal to that microbe. He thought it could be laid down as a general rule that there was no relation between the bactericidal power of serum and the resistance of the animal to the micro-organism. It had been recently demonstrated that the serum of animals protected against the pneumococcus was a far better cultivating medium for that organism than was the serum of similar animals not so protected. It was easy to understand why micro-organisms became more virulent when passed through resistant animals, for in them a process of elimination took place, the weaker germs being killed, and only the more hardy of the race surviving; there was no evidence, however, to show that the fluids of a living resistant animal took any share in this attenuation of the virus. In conclusion, he said that he believed the only process essential to resistance or so-called immunity was the power the cells possessed of taking into their interior and destroying micro-organisms, though Metchnikoff and his pupils had never said that this was the only cause of increased resistance.

Mr. BALLANCE said that the question of immunity had an especial and weighty interest for surgeons, whose daily occupation was the making of wounds, which, if they were not rendered immune against the attacks of micro-organisms, might seriously imperil life. This immunity was attained as the direct outcome of the actions of the living cells and fluids in the neighbourhood of the wound. The surgeon could only aid the natural processes by employing means calculated either to prevent the entrance of, or to destroy, or to inhibit the action of, those deleterious things which could thwart the struggle of the injured tissues towards the attainment of immunity. The healing of the body against the more generalised specific diseases was comparable with the processes employed by nature in the healing of wounds. The presence of pathogenic micro-organisms or their poisons in the body constituted, in one sense, really nothing more than the presence of a foreign body, which it was the function of the natural processes to get rid of. The observation, then, of the manner in which nature could absorb and remove foreign material in wounds would to some extent aid us in the study of similar processes when engaged in warfare against disease. He had been assisted by Professor Sherrington in studying the question of repair, and they introduced small Ziegler chambers into the subcutaneous tissue and peritoneal cavity of certain animals. In the chambers, in the tissue around the chambers, as well as in the normal tissue-plasma and normal peritoneal moisture, they found two distinct kinds of cells. The one kind resembled in all respects the leucocyte; the second kind was much larger, and possessed a large oval vesicular nucleus, which stained faintly, and the protoplasm of the cell body was markedly granular. Both these kinds of cells migrated into the chambers, but there was a definite sequence of events—the leucocytes commencing to enter the chamber shortly after it was implanted in the body, whilst the larger corpuscles (which sections of the inflamed tissue around showed to be the daughter cells of the surrounding connective-tissue corpuscles) did not commence to invade the chamber until some eighteen hours had passed. Briefly, the subsequent events observed were a loss of vitality of the small kind of cell and its inclusion in the vacuole of the larger kind. The larger kind, when all available food in the shape of fibrin and blood-corpuscle had disappeared, commenced to lengthen out and spin fibrous tissue. The less nutritious the more inert the foreign body, the sooner did the amœboid tissue cells become fixed. They were greatly assisted in the interpretation of the appearances seen in the osmic fixed preparations by the processes described by Miss Greenwood in the Phizopoda. Just as in her interesting observations little monads coexisting in the same water as amœba proteus were by it ingested, so the leucocyte became the prey of the amœboid connective-tissue cell. In the chambers we observed giant cells formed by the fusion of connective-tissue cells, or by nuclear multiplication without actual separance of the daughter cells from the parent. These giant cell formsseemed especially to be present when the substance to be absorbed was more resistant than usual. We arrived, then, in this way, at the conclusion that the invading leucocyte had only a temporary purpose to fulfil in the healing of a wound. The rush of leucocytes which occurred towards a spot invaded by micro-organisms might be thought of as useful in various ways:—(1) Though of feeble vitality, they might be able to digest and destroy certain of the foreign organisms; (2) by the death of others a ferment might be set free, which might diminish the vitality of some of the bacteria, and thus caused them to be an easier prey of other cells; and (3) abundance of food (in the shape of leucocytes) for the after-coming connective-tissue corpuscles would be associated with the attainment by them of the highest degree of vigour and vitality. All the main work, then, in wounds, not only with regard to repair, but with reference to the removal of foreign bodies, such as clot, ligatures, micro-organisms, &c., fell upon the connective-tissue cell. Their observations gave no countenance to the old Cohnheim doctrine of the development of leucocytes into connective-tissue cells. The legitimate succession of cells was now a well-established law in pathology, as well as in embryology, and, according to this, tissue was never produced by substitution of function. No positive proof had yet been furnished that the elements of the blood took any active part in the restoration of lost parts. It did not appear reasonable or logical that such an indifferent cell as the leucocyte should ever become transformed directly into a fixed tissue cell, and it was still more improbable that it should be possessed with such a diverse vegetative capacity as to undergo a transition in one place into a connective-tissue cell, in another into bone, and still another into muscular fibre. And if leucocytes in the healing of wounds had a subordinate function to fulfil, it was probable that they had a subordinate place in the fight against disease and in the attainment of a state of either natural or acquired immunity. In the formation of an abscess it was not the leucocytosis to the part which arrested the disease, but the wall of connective tissue formed around the infected spot by the aftercoming connective-tissue corpuscles. The speaker then discussed the question of the action tissue cells had upon substances outside themselves, and gave his reasons for believing that these cells furnished to the body fluids their bactericidal power. The death of leucocytes, which was always occurring, might be thought of as setting free into the body-fluids fibrin ferment, and fibrin ferment (if it existed) must be closely allied to Hankin's anti-toxic substance and Wooldridge's tissue fibrinogen. Clearly, whatever was in the fluids of the body must come from the cells. The normal physiological activity of the cells of the body might thus possibly explain the defensive action of the healthy tissues and fluids against bacterial infection. This clearly existed, for to produce disease a definite dose of micro-organisms must be administered. The normal quantity of anti-toxic substance present during any given period might perhaps correspond to the anti-toxic substance present in the food vacuoles *plus* the quantity secreted from the surface of the cells into the surrounding fluid. If, on the other hand, it were proved that living serum and plasma were not bactericidal, it followed that the anti-toxic substance was a weapon only used under conditions of irritation or emergency by the cell. It might be that an increase in the normal physiological activity of the cells, acquired as a habit, might explain, to some extent at least, some of the varieties of immunity. In conclusion, he desired to express the opinion that, however beautiful the researches might be that were conducted by the aid of the microscope alone in revealing more of the activity and life of cells, yet that in this way we should not progress far on the road towards a true knowledge of the intimate pathology of immunity. The problem of immunity was essentially a chemical one, and its solution must be sought in the laboratory of the chemist.

Dr. E. H. HANKIN said that all previous speakers had taken one or other of the two sides of the question under discussion, but he believed that it was perfectly possible to take a middle course and combine the two opposite theories. There was a good deal of evidence to support the view that if an animal was naturally susceptible, very little phagocytosis occurred, and *vice versâ;* and on the other hand there was a certain amount of evidence that, after immunity had been acquired, the fluids of the body possessed bactericidal power. It was a pity that those who belonged to the school of solidists seemed to imagine that every additional piece of evidence bearing out the truth of the theory of phagocytes was of necessity evidence against the humoral theory, and similar reasoning had been adopted by those of the opposite camp. It appeared to him that the phagocyte theory was much like that put forward to explain the power of the magnet, and like it, though it was not the

Digitized by Google

ultimate explanation, and did not contain the whole truth, had yet been of service, and had led to good results. He desired to discuss in a somewhat polemical way certain criticisms which had been made against his work. It had been asked if there was any evidence that elexin was a definite chemical body, or was it only a hypothetical body supposed to exist in fluids possessing bactericidal powers? He reminded them that elexins were probably proteids, and, like most proteids, were excessively difficult to obtain in a pure state. Many observers had shown that blood serum possessed a certain power of killing bacteria, and that this substance existed in small quantity, and was probably allied to the fibrin ferment. Some time later Halliburton isolated a body which he called cell globulin β, and which he thought was identical with fibrin ferment. By putting two and two together the speaker came to the conclusion that the proteid of Halliburton was the bacteria killer, and he did his best to obtain this body in a state of purity. Dr. Wright had suggested that these elexins were identical with the tissue-fibrinogen of Wooldridge; but there was much evidence to produce against this view. They had, for instance, exactly opposite effects as to clotting, and he was prepared to give many other reasons as to his belief in the non-identity of these two bodies. He then dealt at length with the criticisms of his work by the French investigators; they had repeated some of his experiments and obtained different results, but they had not used cultivations of the same virulence as his own. They regarded the death of the micro-organism not as due to its being poisoned by the chemical substances contained in the fluid, but rather to a change of the media. This he considered as tantamount to saying that if a man died of poisoning by arsenic he had succumbed to a change of diet. A baby rat's blood had no power of delaying disease or of preventing it; but yet it had just as great a power of attracting leucocytes to the seat of inoculation as that of an adult rat; this was because the blood of the latter contained a fluid of bactericidal power which was lacking in the former.

Dr. SIMS WOODHEAD, in reply, drew attention to the word "immunity," which was used in two different senses in clinical and experimental work. A patient was only exposed to the ordinary chances of infection as usually understood, whereas an animal in the hands of the experimenter was subject to very different conditions, as, for instance, when injected with an organism of specially virulent character. It was well known that under suitable conditions an organism might become much more virulent than usual. In the case of the tubercle bacillus, if it were injected into the peritoneal cavity of an animal, which was ordinarily insusceptible to the bacillus, tuberculosis could be produced with great certainty. He thought that specificity was to a great extent a question of phagocytosis; that, if an animal was immune, it was due to its phagocytic power. Professor Klein's case of injecting innumerable anthrax bacilli into the lymph-sac of a frog had no analogy, and, as Metchnikoff had stated, the phagocytic power of the leucocytes might in certain individuals be imperfectly developed. With regard to the main question, all the positive evidence was in favour of phagocytosis so far as the earlier stages of infective diseases were concerned, and it was the only theory on which both the experimental and clinical evidence could be explained. There was no real evidence for the humoral theory, and such would always be difficult to get. Results obtained with serum, which was a product of dead blood, could not be assumed to hold good for living blood. He quoted some experiments of Pflüger's, in which, after injection of peroxide of hydrogen into the blood of a living rabbit, no effect was produced so long as no blood escaped; but, if a single drop exuded, an evolution of gas occurred, not only in that drop, but throughout the blood of the animal. Again, freshly drawn pus had bactericidal properties which disappeared after the pus had stood for some time. These experiments showed how delicate was the substance with which we were dealing. Klein's fluid, obtained by dialysis through collodion from the lymph-sac of a frog, ought not to be considered as exactly the same as the lymph from which it was drawn; yet results obtained with this fluid were taken as holding good for the fluids of the living animal so far as its bactericidal powers were concerned. He could not agree with Klein's statement, that bacilli got into the leucocytes to avoid the bactericidal blood-plasma, for many of them were non-motile, and could not possibly push their way into the leucocytes. If a paralysed lamb disappeared in the neighbourhood of a lion, it would be only fair to accuse the latter of some active part in the transaction. He firmly believed that the discussion, if it had not brought to light much new truth, would yet open up many new paths for investigation.

Sir GEORGE HUMPHRY, having thanked those who had contributed to the discussion, congratulated England on its rising school of bacteriologists, who had accomplished so much, though having great disadvantages to contend against, owing to the false sentimentalism and prejudices against the true interests of humanity which existed in this country. Though he expressed himself as unable to sum up at all adequately the points of the discussion, yet he desired to offer the impressions the remarks of the speakers had made on his own mind. Zymotic diseases were dependent upon the introduction of micro organisms into the system, and these microbes possessed the power of rapid propagation, and exerted a pernicious effect upon the organs of the body. They produced, moreover, certain excreta or toxines, which, even more than the microbes themselves, were prejudicial. The microbes and their toxines could not be dissociated; they both came into contact with the cells of the body, and with the body fluids. These body cells were undergoing continual change—change essential to their vitality, absorbing, modifying the material absorbed, and returning what was excreted into the fluids around. All body cells were phagocytes; that was an essential feature of their existence. But they were promiscuous feeders, and would take up other things besides those normally supplied from the blood—they would absorb foreign matters—they would certainly absorb bacteria. Speaking technically they were phagocytic as regarded the bacteria with which they came in contact, and there was abundant microscopical evidence of this, that they could exercise a solvent or destructive influence upon them. By far the majority maintained that the cells were an important element in the destruction of bacteria. Professor Burdon-Sanderson had found it difficult to conceive that there could be any special function in cells by which they could exert this malignant influence upon bacteria. But it was not necessary to assume that they were specially bactericidal; they were only phagocytic to bacteria by virtue of their general phagocytic qualities; it was a part of their general natural function, and not a special endowment. There was evidence that certain poisonous elements introduced into the blood did tend to attract leucocytes into their neighbourhood. In some cases the cells, so attracted, overpowered and destroyed the bacilli; while in other cases they failed to do so, and the microbes spread over the system. In such instances cells might be found packed with microbes, the latter afflicting the former with such an indigestion as to cause their death. On the whole, the general result of the discussion seemed to be in favour of the phagocytic action of leucocytes and other cells upon bacteria. A much more difficult question was the effect of the body fluids upon the bacilli and their toxines. In considering that we passed out of the range of ocular inspection and almost beyond the range of chemical examination, we had to deal with fluids of very peculiar composition and very great instability. It was found that the fluid serum in the test-tube might be fatal to a micro-organism, and yet inject that microbe into an animal from which the serum was obtained, and it would flourish there; this showed with what delicate materials one had to deal. In this part of the discussion it seemed to him that the probability was in favour of the humoralistic view. But the fluids and the solids of the body interacted so intimately each upon the other that there could be no such thing as solidism and humoralism separately. Anything that could affect the blood serum must also produce an effect upon the cells and the bacteria in it. The toxine of the bacteria diffused throughout the blood serum must exert some pernicious effect upon that serum as well as on the cells, and the serum so altered might finally react on the bacteria, and we must not assume that there was no effect because we could not demonstrate it. All the results he had spoken of so far had been obtained by experiment upon animals, but Dr. Bristowe had thrown some practical light upon the subject. He had remarked especially upon the resistance offered to the entrance of bacteria to the body, and referred to the probability that they became altered in their passage. When we considered the utterly inappreciable evidences there were to account for the degree of immunity possessed by different persons, we should not be surprised that it was surpassingly difficult to trace out the causes of immunity in different

Digitized by Google

animals. He regarded it as almost hopeless to form an idea of the essential nature of the change which produced immunity from small-pox by vaccination. He regretted that the point of exhaustion had been rather summarily excluded from the debate. The manner in which a disease attacked one part, ceased there, and passed to another was difficult to explain on any view, phagocytic or other. The migration area in the course of a common cold was an instance in point. He referred to the phenomena of scarlatina, its incubation, its sudden accession, the sequence of phenomena to quiet subsidence, and, if not fatal, the immunity of the subject for a period. How was this explained by phagocytosis or any other theory? To what influence did the microbes succumb after having obtained a maximum of power? Was it because of some poison which they themselves engendered, or because they had exhausted the pabulum upon which they existed? It was difficult to explain the course of certain diseases of the skin by any theory of phagocytosis. We might rest assured that the interest in this subject had not yet passed away, for many of these problems were still invested with uncertainty, and that uncertainty was an invitation to work yet to be done.

The following card specimens were shown:—

Mr. J. J. CLARKE: (1) Cystic Mamma; (2) Colloid Carcinoma.

Dr. H. D. ROLLESTON: (1) Large Sebaceous Cyst in Brain; (2) Vermiform Appendix and Enterolith.

MEDICAL SOCIETY OF LONDON.

The Treatment of Diabetes.

AN ordinary meeting of this Society was held on March 14th, Dr. Allchin, Vice-President, in the chair.

The customary votes of thanks were unanimously accorded to the retiring president and to the officers and members of the council.

Dr. RALFE read a communication on certain questions in the Treatment of Diabetes. He said that the points which he wished to submit for consideration were—(1) in cases of confirmed diabetes running a protracted course: might any relaxation from the usual dietetic restriction be permitted? (2) in such cases at what period of the disease should opium or its derivatives be commenced, and how far might the drug be pushed? The first question might be considered superfluous were it not that of late certain relaxations had been introduced, chiefly by continental physicians, proposed partly with a view of improving general nutrition, and also to prevent the dangers arising from the accumulation of morbid products, the result of a purely proteid dietary. Dr. Ralfe divided these cases of confirmed diabetes into two classes: 1. *Alimentary*, in which the sugar was at first entirely removable by dietetic restrictions, and was probably entirely hepatic in origin, but in which, after a time, the glycosuria failed to be entirely removed by restricted diet, and a portion of sugar remained non-removable. 2. *General*, in which, from the onset, only a portion of the sugar was reduced by diet, the remainder being non-removable by any amount of restriction. This form of diabetes had usually a neurogenic origin, and was also observable in the so-called cases of pancreatic diabetes. With regard to the origin of this non-removable sugar, it did not proceed, the author thought, entirely from the metabolism of the proteid elements of the food, as had been taught, but from the transformation of the glycogen held in the other tissues and organs of the body beside that of the liver, either by a general lowering of the power of sugar assimilation in the body by the continued passage of sugar into the circulation, or, as some had recently thought, owing to the loss of a sugar-destroying ferment in the blood—glycolytic, normally furnished by the pancreas and other glands. Dr. Ralfe then proceeded to state that observations he had made led him conclusively to the result that in purely *alimentary* diabetes any addition, however slight, of starchy or saccharine food to the diet still further lowered the assimilative processes in the liver, and caused an exacerbation with respect to the amount of sugar excreted, whilst in the *general* form any relaxation of diet led to an increase in the "non-removable" sugar, showing that the disease was assuming a more serious form. In one case in which on strict diet the proportion of removable sugar was as 5 to 1 non-removable, it became after a short resumption of mixed diet only 1 to 1·6. Having shown that a relaxation in diet always aggravated the disease, the author went on to prove that the relaxations proposed were insufficient to combat any theoretical dangers resulting from a proteid diet. The modicum of bread, milk, mashed potatoes, and sub-acid fruits proposed were insufficient in themselves to restore the balance, whilst they contained sufficient sugar to materially injure the patient. Instead of such relaxations Dr. Ralfe was in favour of lowering the amount of proteid taken, of which he showed the diabetic often takes too much, and of increasing the green vegetable food, which is frequently much neglected. Massage, too, also powerfully aided the assimilation of the proteid food. With respect to the second question, Dr. Ralfe remarked that there were no rules regarding the administration of opium and its derivatives, some giving it early, some late, some not at all. Nor was the character of the opiate best suited for administration yet finally decided on; for whilst Dr. Pavy advocated codeine, Dr. Mitchell Bruce had recently put in a claim for morphine. Nor was there any reliable information as to how far the drug might be pushed. The author endeavoured to answer these questions by the light of his own observations, and was of opinion that opium and its derivatives should not be administered so long as the glycosuria could be entirely controlled by diet; but as soon as the sugar was not entirely removable by the strictest of diets, then opium should be commenced, and might be safely increased as long as the excretion of sugar continued to fall under its administration. The signal for stopping any further increase of the drug was when no further fall took place, when an increase was made, or when an actual rise took place in spite of it. Dr. Ralfe also made some remarks regarding the individual preferences of some patients for special preparations of the drug, the greater tolerance of some than others for it, and the best time, as regards food, for its administration.

Dr. PAVY, having congratulated the author on the excellence of his paper, said that the views put forward did not exactly correspond with his own. He would lay more stress upon dietetic measures than Dr. Ralfe appeared to do. He regarded diabetes as essentially the faulty assimilation of the carbo-hydrate elements of food. The fact should not be lost sight of that glycogen and sugar were universal constituents of the body. Carbo-hydrate material might be locked up in proteid compounds, such as the glucosides. Mucin, which existed extensively throughout the body, had comparatively recently been demonstrated to be a glucoside, a complex proteid molecule consisting of a simpler proteid in combination with a carbo-hydrate. As he looked upon all diabetes as being due to defective assimilation of carbo-hydrate matter, he could not follow the author's classification. The statement often made, that the liver was more saccharine than other organs of the body, was not true; nor was it true that the portal vein contained less sugar than the hepatic vein. He had performed a great number of experiments with a view to determine this point, and in all instances he found that the portal vein contained much more sugar than did any other vein in the system, and therefore, if blood of the same quality as the portal blood circulated through the body generally, it would certainly invariably give rise to diabetes. The amount of sugar found in the urine was always proportionate to the amount of sugar at the time in the blood. A trace of sugar could always be found existing in normal urine, which corresponded precisely with the amount found existing in the general circulation. A deviation in the amount of sugar in the urine would indicate a deviation of the blood in this respect from its natural state, and in proportion to its deviation from this natural state would be the impairment of the health of the patient. If his views were correct, it followed that the first object in treatment should be to bring back the blood to its natural state. In some cases there was actually a return of assimilative power, but this would never come about if the urine were permitted to contain much sugar. His habit with those patients whose assimilative power was gradually being restored was to give them some carbo-hydrate, at first in very small quantities, and then gradually increase it, taking the urine as a guide, and keeping it free from sugar. The kind of carbo-hydrate material administered was perhaps not of much moment, but it should be remembered that substances like cane sugar were more irritating than the starches. Given a patient under diet in whom the assimi-

Digitized by Google

lative power was being restored, a safe indication of this was to be found in the fact that when the restoration was beginning the patient would commence to lose weight, though previously, under the same regimen, he had been gaining weight. In the case of people beyond middle life, where the assimilative power was not restored, they would keep on a restricted diet for years and not lose weight.

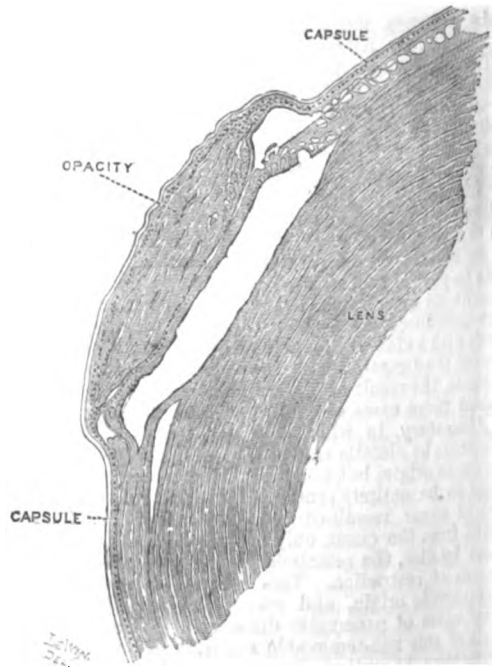
Dr. LAUDER BRUNTON was glad to hear that Dr. Pavy believed there was a certain percentage of sugar in ordinary healthy urine. For his own purposes he had divided these cases into the true diabetics and the gouty glycosurics; the former were usually thin, nervous people, and in them the disease began early in life and ran a rapidly fatal course. In the second category the patients were usually of middle age, full habit, robust frame, and red face. The disease usually yielded readily to diet and exercise, and when the sugar went from the urine it was generally replaced by oxalates or uric acid. He referred to the case of a lady aged eighty-five who for thirty years had passed a quantity of sugar in her urine, but she was still healthy and strong. Though there were these two distinct classes, yet he had often met with mixed cases. In the second variety he had found the administration of salicylate of soda of more benefit than that of opium. He referred to an article which he wrote many years ago in Reynolds's System of Medicine, in which he rather threw cold water on the skim-milk treatment of diabetes. He desired now to correct that criticism, and to state that he had found this treatment very useful, especially in cases in which the glycosuria was combined with albuminuria; in such instances it gave sometimes very good results indeed. He advocated, as an article of diet useful to diabetic patients, the *pommes de terre frites*, as cooked in France. They were not really fried, but the potatoes were cut in very thin slices, thrown into boiling oil, which browned them at once, and then they were taken out and dried. As a rule English cooks, in attempting to make this dish, did not use enough oil, and they did not allow it to heat enough. They served excellently to relieve the monotony of a purely proteid diet. In hospital practice he had been accustomed to prescribe for diabetic patients a draught containing iron and morphine, which he had found very useful in those cases in which it was impossible to carry out a rigid system of diet. But more than one case had ended fatally under this treatment, although the morphine only amounted to three-sixteenths of a grain in the twenty-four hours. He had now made it a rule never to administer morphine if the aceto-acetic reaction with perchloride of iron were present in the urine.

Dr. MITCHELL BRUCE agreed in the necessity of endeavouring to lay down definite rules to follow in particular cases. First, as to the time when opium should be commenced, he did not think it necessary to begin to administer opiates until the dietetic treatment had been exhausted. As to the form of drug which should be chosen, no doubt many cases were better treated with opium than with the pure alkaloids; but he himself had selected morphine because it was a definite substance, and its dose could be so easily regulated; and of the salts he had chosen the acetate in order that he might administer it subcutaneously if he wished to. It should not be given sparingly if all were going well, but it was unwise to push it to extremities in order to rid the urine of the last small quantity of sugar which it contained; it was most difficult to get rid of the latter, and it was foolish to try to do it by means of an increase of the remedy.

Mr. STILLINGFLEET JOHNSON said that he believed that there was no sugar whatever in normal urine. The reducing agent was certainly removed from urine by precipitation with mercuric chloride, which latter would not precipitate sugar.

Dr. ALLCHIN demurred to the common belief that the analysis of the urine from day to day was an exact index of the effect of the diet on the patient, and in the older chronic cases the amount of sugar passed was far from being an exact index of the state of the patient's health.

Dr. RALFE, in reply, thought that they were all very much in touch upon the question of restriction of diet. Dr. Pavy, however, had mistaken the drift of the paper, which was to insist strongly on dietetic measures, as also to point out that the glycosuria might be furnished by the carbohydrate element in proteid tissues. His paper had no reference to cases in which the assimilative power was restored, and he agreed that there were so many cases of all grades that it was exceedingly difficult to classify them. Of the opium preparations, he relied upon morphine as being a more definite substance than codeia, though he often combined it with advantage to some other preparation of the drug.



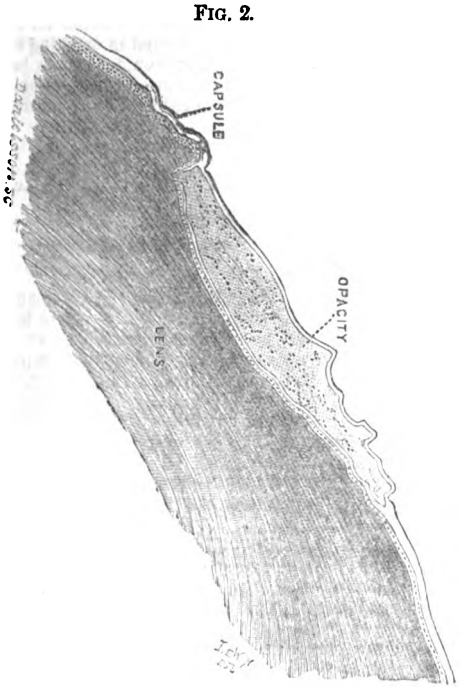
OPHTHALMOLOGICAL SOCIETY.

The Minute Anatomy of Pyramidal Cataract.—The Physical Factor in Conical Cornea.

AN ordinary meeting of the above Society was held on Thursday, March 10th, the President, Mr. Henry Power, F.R.C.S., in the chair.

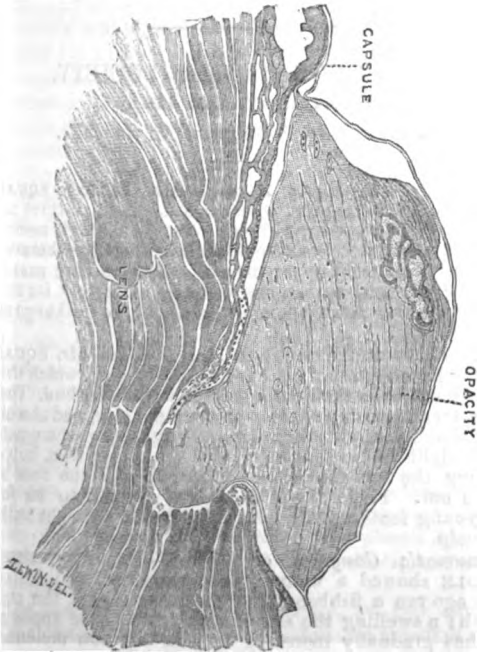
Mr. TREACHER COLLINS read a paper on the Minute Anatomy of Pyramidal Cataract, which was illustrated by a number of photomicrographic lantern slides. He described six cases which formed a series with relation to the date of formation of the cataract and that of excision of the eye. The most recent was one in which the opacity was of less than six weeks' duration, whilst in the oldest it had existed for twenty-one years. The earliest changes were shown to consist in a localised proliferation and breaking up of the epithelial cells which line the hyaline capsule at the anterior pole of the lens, with some elevation of this capsule. (See Fig. 1.) There was also some breaking up of the lens fibres immediately beneath these proliferated cells, which gave rise to shallow excavation of the lens substance. Pyramidal cataracts of longer duration were found to have a layer of cells between the opaque part and the unaltered lens substance. These were continuous with and apparently derived from the cells lining the anterior capsule elsewhere. (See Fig. 2.) In two cases of some

FIG. 1.



years' duration there existed between the opacity and the lens substance, in addition to the layer of cells, a layer of hyaline capsule, apparently secreted by the cells. Mr. Collins thought these cases helped to explain the readiness with which these opaque portions sometimes became detached on being touched with a needle, for such a slight disturbance only completed a separation which had already been partially effected by natural means. (See Fig. 3.) He considered that they also threw some light on the development of the lens capsule, for if the epithelial cells lining it were capable, on the application of a morbid stimulus, of secreting a hyaline layer identical in all respects with it, the inference that the capsule was originally formed by such a secretion seemed a reasonable one. Mr. Collins challenged the statement which had been made, "that in the majority of cases pyramidal cataract was found associated with a perfectly transparent cornea." This, he thought, could only be proved or disproved by the pathological examination of a large number of eyes with opaque cornea, and he questioned if this had been done by

Digitized by Google



those responsible for the above assertion. In his six cases the cornea was the seat of old or commencing opacity.—Mr. TWEEDY referred to the rarity of opportunities for the microscopical examination of pyramidal cataract. He exhibited a sketch he had made many years previously of the appearance of the lens

FIG. 2.

capsule in the case of a child with perforation of the cornea and escape of the lens in the course of ophthalmia neonatorum. He was of opinion that an inflammatory deposit first occurred upon the lens capsule, and set up an intra-

FIG. 3.

capsular cell proliferation. He was opposed to Mr. Collins, view, that the lens capsule was entirely derived from the cells lining it, and thought that its origin was partly epiblastic and partly mesoblastic. He had only once seen a case of pyramidal cataract with perfectly clear corneæ.—Mr. NETTLESHIP mentioned a case in which he had made sections of a lens affected with pyramidal cataract, and found that the capsule passed in front of the opacity. He could not say whether the capsule was split into two layers, as in some of the specimens shown.—Mr. COLLINS, in reply, said he would divide cases of opacity at the anterior pole of the lens into three groups, and to only one of these could the term "pyramidal cataract" be properly applied. He maintained that the structure of the lens capsule and the character of the diseases which affected it were evidence of its epiblastic origin.

Mr. TWEEDY, in relation to the Physical Factor in Conical Cornea, made a communication to the Society, in extension of some remarks by him at the previous meeting. He alluded to several theories that had been put forward in explanation of the causation of this curious disease, such as—(1) increased intra-ocular pressure; (2) malnutrition and atrophy of the central part of the cornea; (3) diminished power of resistance; (4) inherent weakness of the corneal structure. The last hypothesis he thought was most in conformity with observed facts, and this inherent weakness he considered was best accounted for by imperfect completion of the developmental processes. In early fœtal life the gap in the embryonic cornea, caused by the involution which gave origin to the lens, was filled up by cells, beneath which was a homogeneous layer. Into this layer an intrusion of mesoblast took place, and, extending centripetally, gradually closed over the central part, which was the last to be formed. This mesoblastic tissue was the fœtal cornea, and the physical factor in conical cornea consisted in the imperfect growth of the central portion of this layer. No other explanation, he thought, would account for the conical shape assumed by the cornea in this affection.—The PRESIDENT asked if Mr. Tweedy's hypothesis would explain the onset of keratoconus in adult life.—Mr. BRAILEY mentioned that he had once made a microscopic examination of a portion of conical cornea removed by operation, and found a small cavity just beneath the epithelial layer. He referred to the fact that conical cornea in some cases developed for a time, then appeared to become stationary, and subsequently underwent rapid increase.—Mr. TWEEDY, in reply, said he did not wish to exclude the agency of other factors in the causation of conical cornea, but merely to draw attention to what he thought was the true physical one.

The following living and card specimens were shown:—

Dr. ROCKLIFFE (Hull): Case of Unilateral Proptosis.

Mr. HARTRIDGE: Case of Double Lacrymal Fistula.

Mr. WORK DODD: Case of Scleroderma of Lower Eyelid and Cheek.

Dr. D. J. WOOD: (1) Disease of Retina and Choroid, with Detachment of Retina; (2) Double Congenital Coloboma in Fundus.

Mr. TAY: Bleaching of Eyelashes and Eyebrows in Sympathetic Iridocyclitis.

Mr. LAWFORD: Reversible Spectacle Frame.

Mr. WRAY: New Vascular Growth in Vitreous.

Mr. HOLMES SPICER: Keloid in Scars of Herpes Ophthalmicus.

MANCHESTER PATHOLOGICAL SOCIETY.

WEDNESDAY, FEB. 10TH.

T. C. RAILTON, M.D., M.R.C.P., President, in the chair.

Birth Palsy.—Dr. RAILTON showed specimens from a case of Double Spastic Hemiplegia in an idiotic boy aged three. There was a history of difficult labour, forceps, and asphyxia. On admission into hospital it was noted that he lay habitually upon his side, with head strongly retracted, the thighs crossed and somewhat flexed upon the abdomen, the feet being extended. All four extremities showed "lead pipe" contracture. The slightest touch produced universal rigidity, so that he could be lifted "all of a piece." When fed, the muscles of the lower jaw were thrown into spasm. There was fine tremor of the hands when raised, and on yawning general clonus occurred. Knee-jerks were exaggerated and the superficial reflexes active. On being held up under the arms he became universally spastic. Death occurred from broncho-pneumonia. The necropsy revealed little alteration in the naked-eye appearance of

Digitized by Google

the brain. There was merely a slight depression, forming a shallow groove, most marked near the vertex, which ran parallel with and involved the pre-central fissure, the fissure of Rolando, and the central convolutions, in both hemispheres. The pia and arachnoid in these regions were thickened, opaque, and adherent. A similar thickening of the pia was found over the temporo-sphenoidal region and at the bases of the frontal convolutions, but no depression. The paracentral lobules were slightly depressed and the pia was thickened and opaque. The base of the brain was normal.

Sections of Whole Organs.—Professor DELÉPINE exhibited a series of transparent and of opaque sections of Brain, Heart, Lung, Liver, Spleen, Kidney, Intestine, &c., and pointed out the advantages offered by this method of preservation, for teaching purposes and for preserving the appearances of lesions. He then described in detail a section of lung, in which the whole organ had been infiltrated with soft pneumonic products, as a result of destructive lesions of the vagi due to aneurysmal pressure. These pneumonic products were full of tubercle bacilli, yet there were no indications, either in the lung or elsewhere, of the formation of any miliary tubercle or of any cheesy products. There was, in fact, a distinct tuberculous infection without any tuberculosis. The bacilli had grown in the pneumonic products just as they might have in a nutrient medium kept in a test-tube, and incubated. Dr. Delépine then briefly described the method of preparing these large sections; it was first described by Professor Hamilton some ten years since.

Fractured Skull in an Infant.—Dr. KELYNACK showed Skull-cap and Brain from an infant of five months, where extensive fracture of the vault resulted from a fall. At the necropsy there was no evidence of external injury. A fracture extended from a little in front and above the right parietal eminence, backwards across the lambdoid suture, into the occipital bone. There was no laceration of underlying dura mater, but distinct subdural clot on the opposite side. The frontal and parietal lobes were covered by an effusion of puriform lymph. No distinct cerebral symptoms occurred at the time of the accident, but convulsive attacks appeared on the third day, the temperature rising to 106·2°. The little patient became comatose, and died four days after the fall. The infant was the subject of early rickets, but otherwise healthy.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

WEDNESDAY, FEB. 17TH.

Mr. ANDERSON, F.R.C.S., President, in the chair.

Typhoid Fever.—A paper on the treatment of typhoid fever was read by Dr. W. E. TRESIDDER. He advocated careful watching, nursing, dieting, and keeping up the patient's strength until the fever had run its course. Drugs were only needed for the treatment of special symptoms. The mortality at the General Hospital, Nottingham, for the year 1890-91 was 6·1 per cent.; eighty-one cases were treated. The preventive treatment might be divided into the prevention of immediate infection and general prevention. The patient should be kept scrupulously clean, tow being used for cleansing instead of lint, sponge, flannel, or pocket-handkerchief. All sheets, blankets, &c., should be put immediately on removal in an antiseptic fluid. The nurse must wash her hands immediately after attending to the patient and before either giving or taking food. As regards general prevention, water companies should be heavily fined for supplying water polluted at its source or in transit. There was necessity for legislative reform in the existing system of the drainage of dwelling-houses. The machinery of compulsory notification was put in motion too late after the disease had got a hold. The landlord of any property should be held accountable for the state of the drainage, and punishable by fine if it were found defective, whether disease had broken out or not. There should be two sets of plans of the drainage of any property—one kept by the landlord and the other at the sanitary offices, where tenants or those about to rent property might inspect it on paying a small fee. Any alterations in the drain system made from time to time to be entered on the plans.—After some remarks from the President, Dr. HANDFORD remarked on the relation of case mortality to the age of the persons affected. The larger the proportion of young subjects attacked, the lower the mortality. While confessing to some disappointment in the results of treatment by β-naphthol, he thought that in the present state of our knowledge of the cause of the disease an antiseptic plan of treatment the most rational.—Dr. BOOBBYER thought carelessness in connexion with dairies was responsible for much evil, while in the country people persisted in drinking water known to be unsafe.—Dr. CATTLE would hesitate before giving purgatives as routine treatment of constipation, but occasionally the administration of calomel was attended by brilliant results.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY

THURSDAY, FEB. 25TH.

Mr. W. F. FAVELL, President, in the chair.

Spasmodic Torticollis.—Mr. ATKIN showed a woman with spasmodic torticollis, for whom six months before he had excised an inch of the left spinal accessory nerve. The relief afforded by the operation was immediate, the patient eating and sleeping better than she had done for months. Unfortunately the symptoms gradually returned in seven weeks' time. The muscle, though weakened, was by no means entirely paralysed by the operation. The cervical nerves were evidently affected as well as the spinal accessory. The only assignable cause of the affection was trouble, the patient being a widow and having a large family to support.

Sarcoma of the Mesentery.—Dr. KERR showed a specimen of a large spindle-celled sarcoma of the mesentery from a man forty years of age, who had been under Dr. Porter's care in the infirmary. The illness had only lasted about ten weeks, during which time the tumour rapidly increased in size, although the discomfort arising from it was comparatively slight. The mass weighed twenty-one pounds, and almost entirely filled the abdomen. The liver and mesenteric glands were infiltrated with nodules of new growth, many of which had undergone cystic degeneration. All the other organs were free from malignant disease. Microscopic sections which were exhibited showed the tumour to be composed of large nucleated spindle cells, intermingled with a few round cells. The tumour was very vascular, the vessels being imperfectly formed.

PLYMOUTH MEDICAL SOCIETY.

SATURDAY, FEB. 13TH.

Mr. T. LEAH (Stonehouse) in the chair.

Congenital Syphilitic Ataxia.—Mr. ELLIOT SQUARE showed a girl, aged nine, whose mother had had three miscarriages. The patient walked in a marked ataxic manner, the tendon reflexes were absent, she had interstitial keratitis, and typical notched upper incisors. For ten days past she has had left facial paresis and deafness of left ear for three or four weeks. Ataxia commenced about six weeks ago and has increased.

Left Traumatic Hemiplegia in a Pigeon.—Mr. SQUARE also exhibited a hen "feather-footed tumbler," which three weeks ago was pecked on the vertex by another bird. There was evident bruising of scalp on the right side, and the bird walked and flew with difficulty. There is now a bare patch on the right half of the vertex, and the pigeon flies, but on walking the left foot slips backwards, and the toes are spread out. There is no depression of skull to be felt, and young feathers are now sprouting on the right half of the scalp.

Traumatic Ganglion of Thumb.—Dr. ANSTRUTHER RENDLE showed a woman, aged sixty-one, who thirteen years ago ran a fishbone into the inner side of the right thumb; a swelling the size of a walnut at once appeared, and has gradually increased in size. It now presents a painless, semi-fluctuating ovoid swelling in the situation of the right thenar eminence—quite superficial and unconnected with bone or tendon.

Reviews and Notices of Books.

A Treatise on Diseases of the Lungs and Pleura. By the late WILSON FOX, M.D., F.R.S. Edited by SIDNEY COUPLAND, M.D., F.R.C.P. London: J. & A. Churchill.

THE appearance of the late Dr. Wilson Fox's book on "Diseases of the Lungs and Pleura" has been awaited with great interest not only by those who remembered him as a beloved teacher and friend, but also by all who knew him by repute as a sound clinical observer who had the power of conveying to others what he himself knew. Now that the work is before the profession we do not think that any disappointment will be felt. Much was expected, but in Dr. Fox's *magnum opus* we find even more than we had hoped for. One who was well entitled to speak of the author's mode of work said that "only those who knew him intimately in his mode of writing and of publishing can be aware of the enormous labour he imposed upon himself in order to secure accuracy and fulness ..... His reading of all literature, past and present, that bore upon his subject was wide, deep, and critical; and the pains which he took to verify quotations by one author from another, whether in monograph, contribution to scientific journals, in this country or elsewhere, was beyond all praise." This thoroughness of research is apparent in all Dr. Fox's writings, but nowhere more than in the present volume. An extensive bibliography is given at the end of the book, but this "only comprises the larger monographs and treatises referred to"; on every page are copious references and quotations from other authors, given as foot-notes, so that the reader is in possession of abstracts of everything worth reading which has been written on the subject under consideration.

Dr. Fox's lamented death occurred in 1887, and the manuscript was therefore not up to date. The arduous duties of editing the treatise were entrusted to Dr. Coupland, and it is a matter of general congratulation that the work fell into such competent hands. He has performed his part in a manner meriting the highest commendation. The additions which were necessary have been inserted with most excellent taste, and in so dexterous a manner that the reader is scarcely conscious of any change of authors. To edit a work of this class and this extent (1200 pages) was indeed a great undertaking, but Dr. Coupland will feel that his labours have not been in vain, for he has presented us with the most complete monograph on diseases of the lungs and pleura now extant.

The various diseases are treated in a uniform manner. Each division opens with a definition of the disease. These definitions are singularly full and precise, and by studying them a comprehensive idea of the subject to be discussed is at once obtained. Then follow the history, etiology, morbid anatomy, associated pathology and pathogenesis, symptoms, complications, clinical variations, prognosis, diagnosis, and treatment. Needless to say, each subdivision is dealt with in the thorough and complete manner characteristic of the author. Diseases of the Air-passages, including acute, chronic, and plastic bronchitis, spasmodic asthma, influenza, bronchiectasis, &c., are first considered.

As regards the Pathology of Asthma, Dr. Fox adheres to the views of Cullen and Laennec, that the spasm of asthma depends upon the contractility of the circular muscular fibres of the bronchi, and that it is essentially spasmodic in character. He says: "Although this view has often been disputed, it has remained the prevalent one up to the present day, and is, I believe, the only one by which the phenomena of the disorder can be adequately explained." With this statement we cordially agree.

The chapter on Bronchiectasis is probably the most complete account that has yet been written on this subject. Those who have studied Dr. Fox's "Atlas of the Pathological Anatomy of the Lungs" will have already formed a high opinion of the author as a pathologist of the first rank, and will not be surprised, therefore, when we lay special weight upon the sections treating of pathological conditions. This is well exemplified in this chapter, where the mechanism bringing about the dilatation of the bronchi, and the condition of the tubes themselves, are described in a most masterly manner.

We now pass to the main division of the book, Diseases of the Lungs. One of the first points that will strike the reader is the exhaustive manner in which some subjects are treated which are usually passed over in a few pages. Especially is this the case with Gangrene of the Lungs, to which no less than forty-two pages are allotted. Most interesting also are the chapters on Collapse of the Lungs, Pulmonary Embolism and Thrombosis, and Diseases due to Inhalation of Dust.

Dr. Fox's style of writing is charming, and tempts the reader to linger over the pages, every one of which is full of interest. We would particularly draw attention to the vivid description of the symptoms of pulmonary embolism and thrombosis. The way in which the pathology and pathogenesis of emphysema are described is another example of the detail with which every feature of the disease is worked out.

Those who have consulted Dr. Russell Reynolds' "System of Medicine" will be already familiar with the articles on Pneumonia and Broncho-pneumonia, although for the purposes of this work they have been subjected to a most thorough revision. Although with the development of bacteriology our knowledge of the causes of diseases has greatly increased, Dr. Fox's views as regards the etiology of pneumonia were much the same as are held by most authorities at the present time. He says: "It can hardly be held that acute pneumonia in its ordinary manifestations is a common inflammation; a blood state, either engendered within or without the body, is absolutely necessary to explain its occurrence. Its main characters are those of a general and not of a local disease." Again, after comparing the causation of pneumonia with that of typhoid fever and diphtheria, he says: "To sum up this subject I believe that the evidence at present existing tends to show that pneumonia may arise from miasmatic influences of the pythogenic kind, and that it is very possible that this may be the origin of a large proportion, if not the whole, of the cases of acute primary pneumonia."

We turn to the section on Phthisis with a great deal of interest. It was Dr. Fox's favourite study. Readers of the "Atlas" will know what a complete grasp the author had of his subject, and his clinical knowledge was no less profound than his pathological. The subject of tuberculosis of the lungs occupies over 400 pages, and forms a most complete exposition on phthisis. It was written at a time when most of the German observers were promulgating the idea that inflammatory changes were necessary for the development of tubercle. Dr. Fox taught that the tubercle was primary, and some of his remarks penned before the bacillary doctrine was so firmly founded, show what a wonderful insight he had into the etiology and pathology of the "national disease." Thus he says: "It will be apparent from the account which I have already given of the pathology of phthisis, that I do not accept Niemeyer's views, that I believe it to be essentially one disease,

Digitized by Google

and that it is of a tubercular nature"—thus at once declaring his firm belief in the unity of the disease. In speaking of caseation he says: "Neither in my own experience nor in the writings of any author unbiased by a special view of tubercle have the lobular pneumonias been shown to undergo caseation or lead to phthisis, except in the presence of tubercle." Referring to the different appearances of "yellow" and "grey" tubercle, Dr. Fox remarks: "The point on which I would insist is that, whether it be regarded as infectious or constitutional, the different appearances of tubercle cannot be classified separately, according to arbitrary histological definitions; it must, I believe, be regarded as a *disease*, and for this disease a distinctive name is desirable."

As above stated, this article was written in the early days of the germ theory of phthisis; but had it been as firmly established as it is now, the author could hardly have written differently, as witness the follow passage: "It may now be very generally accepted that tubercle can be reproduced by inoculation with tubercle, but with tubercle alone." Again, he recognises a second etiological factor, as is now universally admitted: "As a hypothetical question it may be held that, even if tuberculosis depends exclusively on the effect of bacilli introduced into the body, these may owe their power of germination in certain tissues to the weakening of the latter by disease or other causes." He does not uphold the doctrine of phthisis *ab hæmoptoë* as is shown by several of his remarks. The clinical description of the disease is most graphic, and he enters upon a most exhaustive discussion of all the symptoms. In reference to treatment, he would place climatic conditions first in the category of active measures, but he also lays special stress on prophylaxis. "I believe, however, that the most efficient prophylaxis for phthisis in the future, as in the past, will be found in increasing attention to the sanitary condition of dwelling-houses and workshops, though the discovery of unhealthy conditions, masked as they occasionally are, is sometimes even more difficult in the homes of the wealthy than in houses of less size and pretension."

We have not space to enter more fully on a review of this excellent work. We would willingly have discussed the section on Pleurisy and Empyema, which is one of the most important in the book. The amount of labour expended on it has been immense. We would especially draw attention to the careful and detailed study of the question of paracentesis. The advance of surgery has rendered considerable addition necessary to the treatment of empyema, and for this purpose Dr. Coupland has called in the services of Mr. Pearce Gould, whose large experience in the surgery of the chest renders his remarks particularly valuable. We would cordially recommend all those who wish to extend their knowledge of diseases of the chest to consult this volume, for they will find collected in it an enormous amount of information, presented in the most captivating manner. In addition, this treatise will have a special charm for those who knew the esteemed author and listened to his teaching, as the editor remarks in the preface: "No former student of University College and Hospital can peruse this book without its recalling memories of one who was revered as a teacher, admired as an ideal physician, and trusted as a friend; for surely these pages reflect that earnest seeking after truth, with its minute and painstaking scrutiny of every detail, that discriminating judgment and careful analysis, which were his attributes. One can truly say that 'being dead he yet speaketh' through the pages of this book, and his old pupils should know that the opportunity now given for its perusal is owing, in the first place, to the author's widow, and, finally, to his eldest son."

OUR LIBRARY TABLE.

The Medical Register and Directory of the Indian Empire. By JAMES R. WALLACE, M.D. Calcutta: C. J. A. Pritchard.—This compilation supplies an important want to members of the medical profession, not only in India, where perhaps it is most needed, but also in other parts of the United Kingdom. It is founded mainly on the lines of the Medical Directory of this country, but adapted especially to the requirements of India. It is intended to clear the way for systematic regulation of medical practice in India. It will go far to fulfil its purpose, and to the scattered members of the profession in that empire will provide a social bond by affording definite knowledge of one another's existence. The title explains the nature of the contents. The volume is a monumental record of four months' arduous labour, but of a kind which is certainly not unproductive or merely ornamental. The defects, such as they are, will doubtless be obliterated in other editions.

On a New Cysticercus and a New Tapeworm. By T. B. ROSSETER, F.R.M.S.—In the Journal of the Quekett Microscopical Club, Vol. IV., Series 2, page 361, No. 30, January, 1892, Mr. T. B. Rosseter describes a new cysticercus and a new tapeworm. The cystic form he finds in Cypris cinerea; it is oval, invaginated at the anterior portion, and has a long caudal appendage. The cyst is not fenestrated; the hooks around the rostellum of the mature scolex are constant in number—ten,—and lie in an angular position; they are about $\frac{1}{3\,0\,0}$th of an inch in length. There are four oval suckers, each of which is armed with 132 small hooks, arranged symmetrically in rows around the periphery of the sucker and longitudinally in the centre from the apex to base. These hooks are about $\frac{1}{5\,0\,0\,0}$th of an inch in length. On feeding ducks or drakes (by means of pipettes) with cypridæ containing these new cysticerci, there were developed in the pylorus and part of the duodenum a number of tapeworms about the twentieth of an inch in length. At first sight they appeared most like the tænia lanceolata, but Dr. Blanchard of Paris has come to the conclusion that it must be placed in a new genus, "Echinocotyle"; and he suggests that the special tænia described by Rosseter should be named "echinocotylus Rosseteri."

A Treatise on Practical Anatomy. By HENRY C. BOENNING, M.D., Lecturer on Anatomy and Surgery in the Philadelphia School of Anatomy. Philadelphia and London: Davis. 1891.—We cannot recommend Dr. Boenning's book to English students. It appears to be merely a condensation from other and better text-books. A description of a muscle such as this—"Internal pterygoid; origin, pterygoid fossa; insertion, inner side of angle of inferior maxillary: nerve, inferior maxillary"—will show how little can be learnt from this work, and how scanty is the knowledge conveyed therein, for the other parts of the subject are dismissed in much the same summary style. The illustrations have no more merit than the text, for most of them are reproductions of drawings with which we are quite familiar in some former text-books, and they give us the impression that the blocks from which they have been struck off have now become much worn.

Merck's Bulletin.—With the commencement of its fifth volume the size and the scope of Merck's Bulletin have been very considerably altered. The familiar tinted pages have given way to larger white pages, and the length and the style of the contents have further undergone modification, room being now found for much new material in an unabbreviated form. The profusion of notes of exclamation, which so often distracted attention in the past, seems to have largely vanished before the magic wand of the new editor, Dr. W. H. Porter, of New York. The present aim is ambitious; it is hoped to attract original

Digitized by Google

communications dealing with pharmaceutical chemistry and the physiological actions and therapeutic uses of both new and old remedies, while another section will be devoted to clinical papers in which the practical and chemical side of therapeutics will be discussed. New remedies, formulas, practical hints, and miscellaneous clippings will be represented as hitherto. A section will be devoted to medical dietetics and another to monographs upon "interesting drugs which are attracting the special attention of the medical profession." Many of the original articles in the first number are of great interest—notably that by the editor upon some new observations on the physiological action of the mercurials and iodides. Ichthyol is the subject of very extended notice, monographs from numerous sources being quoted in its interest. The new venture seems well worthy of support, but we hope that in future it will not be found necessary to print "trade announcements" on the same pages with the text.

The Journal of Physiology. Vol. XIII., Nos. 1 and 2. Edited by MICHAEL FOSTER, M.D. The Engraving Company, Cambridge.—The contents of this part are: 1. Warren P. Lombard: Some of the Influences which affect the Power of Voluntary Muscular Contractions, with two plates. 2. E. N. Stewart: The Influence of Temperature and of Endocardiac Pressure on the Heart, and particularly on the Action of the Vagus and Cardiac Sympathetic Nerves, with two plates. 3. W. B. Hardy: the Blood-corpuscles of the Crustacea, together with a suggestion as to the Origin of the Crustacean Fibrin Ferment, with a plate.

The Quarterly Journal of Microscopical Science. Edited by Professors LANKESTER, KLEIN, SEDGWICK, and MILNES MARSHALL. Vol. XXXIII., Part 2. January, 1892. London: J. & A. Churchill.—This part contains six communications. 1. On Onchnesoma, by Arthur E. Shipley, with one plate. The Onchnesoma is one of the Zephyrea. 2. Note on a Sieve-like Membrane across the Oscula of a species of Leucosolenia, with some observations on the Histology of the Sponge, by E. A. Minchin, with two plates. 3. The Development of the Oviduct in the Frog, by Ernest MacBride, with two plates. 4. On the Nauplius Eye persisting in some Decapods, by Margaret Robinson, with a plate. 5. On two Acanthodriloid Worms from New Zealand, by Blaxland Benham, with two plates. Lastly, an article on the new genus of Synascidians from Japan, by Asajiro Oka and Arthur Willey, with two plates.

New Inventions.

NEW GLASS DRAINAGE-TUBES.

THESE are made of glass of such soft consistence that they will readily admit of being bent by the surgeon or assistant into any shape required merely by the aid of an ordinary spirit lamp or Bunsen burner. The tube being held in the flame until well heated, is easily and quickly manipulated into the desired shape; it will rapidly cool of itself down to the temperature of the body. Being absolutely smooth throughout, and having a gently bevelled distal end, any irritation, whether that of insertion, removal, or *in situ*, is reduced to a minimum, and excretion is rendered much more expeditious. Granulations are also not so liable to be injured as they are by the indiarubber tubes, which have less perforations than those under notice. Thus, while ever remaining patent, they collect the discharge from all parts. The perforations themselves, having perfectly smooth rounded edges, neither offer the resistance to the flow nor the injury to granulations that the perforations of the indiarubber tubes are so apt to do. They are provided with a substantial shoulder at the proximal end, designed to prevent them from slipping in beyond reach, and favouring facile manipulation by fingers or forceps, as well as obviating the necessity for any particular fixing scheme, judicious bandaging being all that is required. The tubes should be turned round while heating, so that the whole circumference may be influenced equally. They should be well heated, and but little force applied in bending. The tubes, which have been devised by Mr. Haydn Brown, are made in all sizes by Alexander Kemp and Sons, glass blowers, Edinburgh.

A TRUSS FOR WORKERS.

MR. W. YEATMAN WARRINGTON of Wolverhampton has forwarded to us a truss for inguinal hernia, now used generally by men who work at the furnaces &c. in great heat in the iron-works. He writes: "There is nothing especially new about it, but it is most effectual, does not chafe the skin, and has no spring to corrode by sweating. It lasts as long as three of the ordinary trusses with a steel spring." There must be many members of the profession to whose patients a cheap, reliable, lasting truss would be of service.

THE ROYAL BRITISH NURSES' ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—I desire to thank you for the kind and powerful support which you have always given to the Royal British Nurses' Association, and would ask you to accord me space in your widely-read columns to lay its case once more, very briefly, before your readers. It was founded just four years ago, in order to unite trained nurses for their mutual aid, and so increase their efficiency and usefulness to medical men and the public. It has already been approved and joined by a considerable number of the leading members of the medical profession in this country, and by more than 3000 nurses. It has instituted, and is successfully carrying on, several important schemes to assist its members in their work and in times of adversity, sickness, and old age. Through the efforts of its members in South Africa, a system of Government registration of nurses became law last year throughout the Cape Colony, while in other parts of the British Empire similar legislation is now being sought for. In this country, I need scarcely remind your readers, any woman, even if destitute of knowledge or of character, can term herself a trained nurse. Hospital certificates can be and have been forged or stolen, and by such means unworthy persons can obtain and have obtained positions of great trust, while genuine hospital certificates, once given, cannot be recalled or cancelled, even though the recipient in after years may give way to habits which render her unworthy of trust, or even commits grave offences against the law. And so it is, unhappily, undeniable that such persons obtain employment, bring danger to the sick and discredit on the nursing vocation and on all their fellow-workers. To remedy these grave evils, it was proposed by the Association that trained and duly qualified nurses should be enrolled on a general register to be published annually, and that the names of anyone who might prove to be untrustworthy should be removed from this list. At a cost of great time and trouble, and of about £800, the Association has commenced this work *as a voluntary measure* by publishing a Register, showing the names and addresses of some 1800 nurses, with the places and length of hospital training which each has received. I now venture to appeal to medical men, to whom nurses already owe so much, and who are so deeply interested in securing good nurses, to become members of the Association, and give it their assistance and advice. The by-laws and all other information can be at once obtained upon application to the Secretary, 8, Oxford-circus-avenue, Oxford-street, W.

I am, Sirs, your obedient servant,

HELENA,
President of the Royal British Nurses' Association.

Cumberland Lodge, Windsor, March 15th, 1892.

THE LANCET.

LONDON: SATURDAY, MARCH 19, 1892.

THE newly elected London County Council held its first meeting on Tuesday last, and its committees will shortly be at work, and will doubtless, in view of the recent decision of the electors, continue the policy which was pursued by the recently expired Council. This policy, so far as public health administration is concerned, has been one of unceasing activity, guided by a desire to use to the utmost the powers vested in the Council for the removal of unhealthy conditions from London. We may briefly review the work of the Council in this direction since it first came into existence.

The Council in its early days appointed a medical officer of health, and without loss of time addressed to the several sanitary authorities a circular letter asking for information as to the insanitary areas within their respective districts. This letter evidently met with a ready response, and from that moment the small staff at the disposal of the Council must have been severely taxed, for we learn from the annual statement of the Chairman, Sir JOHN LUBBOCK, that the Housing of the Working Classes Committee had under consideration as many as 200 insanitary areas. Until the end of the year 1890 the Council had, however, no powers other than those under CROSS'S Acts for dealing with this subject, and as a result it could not do more than urge upon the sanitary authorities the desirability of enforcing as far as practicable the provisions of TORRENS' and the Nuisance Removal Acts. Much difficulty had been experienced in working both CROSS'S and TORRENS' Acts, and the first business of the Council was therefore to propose those amendments in the law which were necessary for immediate purposes, and to point out the urgent need for opportunity to be given for dealing with small areas which were not of sufficient extent for the purposes of CROSS'S Acts and were yet unsuited for the application of TORRENS' Acts. The Housing of the Working Classes Act, which received the Royal assent during the latter part of the year 1890, supplied this deficiency and placed the Council in a position to undertake more seriously the work it had already begun.

Under this Act many hundreds of houses actually unfit for human habitation have been closed by the orders of magistrates, and the Council and the district authorities have been confronted with the difficult question whether areas which needed complete clearance should be dealt with under Part I. at the expense of the Council, or Part II., either at the expense of the district authority or at the cost of both. The Act provided that the Secretary of State should arbitrate when this point was in dispute, and the Council at once made the necessary appeal in respect of five areas, two in Shoreditch and three in the district of St. George the Martyr, which had been represented to it under CROSS'S Acts. In each case the Home Secretary, after holding a local inquiry, decided that the Council should bear but part of the expense, and the district authorities were required to effect the improvements and the Council to contribute one-half of the cost of improving the first two areas, and one-third of the cost of improving the last three. Schemes were therefore prepared by the Vestry of St. George's for the improvement of two of the areas in its district, and the Local Government Board held an inquiry last week with a view to determine whether the schemes should be approved.

In numerous other instances steps have been taken for carrying out improvement schemes in various parts of the metropolis, and these earlier negotiations between the Council and the district authorities may be expected very shortly to bear fruit. In one instance the Council decided, after communication with the sanitary authority, itself to carry out an improvement scheme under Part II. of the Act, and the local inquiry ordered by the Local Government Board in respect of this (the Brookes Market Holborn Scheme) was held a few weeks ago.

The Council has as yet prepared only one large scheme under Part I. of this Act. The neighbourhood of Old Nichol-street, Bethnal-green, had long been known as a metropolitan sore. The insanitary circumstances of this locality were clearly brought to light during an inquiry held by order of the Home Secretary some five years ago, and to those who knew this part of London well it was evident that no incomplete method of dealing with it would prove satisfactory. The Council therefore resolved, after representations by the medical officers of health of the districts of Bethnal-green and Shoreditch, to effect this improvement, and prepared a scheme which for comprehensiveness proved that the Council was not disposed to exercise in any feeble way the powers with which Parliament had endowed it. It is a somewhat curious commentary upon health administration in London that the action of the Council in this matter did not in any way give universal satisfaction. One section of the lay press particularly failed to see that the mere closing and repair of houses, assuming this method could have been universally applied to all the houses in this area, would not have brought out the rearrangement of buildings which was necessary. It was evidently not understood that owing to the ownership of these premises being vested in many persons, no other action was possible than that adopted by the Council, and that nothing but the purchase of the property by the metropolitan authority would enable the improvements to be effected which were so urgently needed. The Housing of the Working Classes Act of 1890 had, moreover, provided more favourable terms for a local authority purchasing insanitary property under these circumstances, and it was very necessary that experience should be gained in the shortest time of the usefulness of the new measure. It may be expected that this scheme will give ample opportunity for this purpose, and the future action of the Council may to some extent depend upon the results of this large undertaking.

So far therefore in the year and a half which has elapsed since the Council obtained its powers under the Housing of the Working Classes Act, the important work of steadily

Digitized by Google

improving London has been undertaken, and we sincerely trust that it may be continued until the worst of the London slums have been finally removed.

THE settlement of the action "STEELE *v.* SAVORY" has proved advantageous to the cause of progress at the Royal College of Surgeons of England. It has removed an obstacle which blocked the path of reform. It has established the validity of the Charter and By-laws, and thereby terminated a condition of uncertainty which led to developments not calculated to conciliate the governing body of the College. It has diffused a glow of quiet satisfaction through the breasts of the members of the Council of the College, and has disposed them to seek peace by conciliatory measures. It has opened out to the Fellows of the College a prospect of early improvement in their status and constitutional importance which will ultimately prove beneficial to the Members, and it has now resulted in the Council of the College proclaiming an amnesty for the thirty-one Members of the College who had the courage or temerity to infringe Section xvii. of the By-laws in February, 1889. The exact situation of affairs is readily grasped on perusing the minutes of the proceedings of the Council on March 10th. In our article on March 5th we mentioned that on Feb. 11th the Council of the College had deferred the consideration of the infraction of By-law xvii. till March 10th, and resolved to inform those concerned in this infraction of the intention of the Council. The intimation of this intention was conveyed to them in a letter from the Secretary of the College, with the result that a large majority responded to the letter, and generally in a manner which satisfied the President and Vice-Presidents to whom the documents were in the first instance submitted. A few did not reply, but the doctrine of supererogation appears to have been adopted by the representatives of the Council and the fund of merit formed by the contents of the approved letters was sufficient to allow of a dividend in favour of those Members who had perhaps been influenced by the proverb that "speech is silvern, but silence is golden," or had been deterred by some hidden fears from even acknowledging the receipt of the Secretary's letter. However this may be, any intention which may have existed to vindicate further the authority of the Council and the By-laws was abandoned, and the Council adopted unanimously the following resolution: "That the Council, after full consideration of the infraction of Section xvii. of the By-laws by certain Members of the College who took part in the attempt to convene an illegal meeting, hereby determine to take no further action in the matter." This decision will, we think, meet with very general approval. Had the Council drawn a distinction between those who acknowledged their mistake and expressed regret and those who declined to do so, it might very probably have drifted into the ludicrous position voluntarily assumed by that celebrated official DOGBERRY, when charging the watchman to "comprehend all vagrom men" and "to bid any man stand in the prince's name":—

Watchman: How if he will not stand?

Dogberry: Why then, take no note of him but let him go; and presently call the rest of the watch together, and thank God you are rid of a knave.

As it is, the Council has as much reason to be grateful to the majority of the thirty-one Members for replying so courteously to the Secretary's letter as those Members have for the act of grace which the Council has unanimously passed.

The termination of a struggle which has dragged its slow length along for more than three years has reopened the questions of constitutional reform which had been suspended by the action of the Members against the Council. It could not well be expected that, under the circumstances, the claims of the Members of the College to a voice in the management would have in any wise been recognised by the Council after frequent denials of such claims and the repetition of the opinion that they ought to be allowed to rest. The Council is not like Archbishop CRANMER, of whom it was said, "Do my Lord of Canterbury a shrewd turn and he will be your friend ever after." Even if the Council were convinced of the propriety of making concessions to the Members, human nature might stand in the way for a time; but, so far as we can judge, there are only a few of the Council who are prepared for any concession, and possibly all of these few would not have the courage of their opinions and face the opposition with which they would be met. The time of the Members has not yet come in the Council, but with the Fellows it is different. The Council has acknowledged their claims to be consulted, and is probably anxious to meet their wishes. At all events, it has lost no time in redeeming its implied pledge to take the case of the Fellows into consideration as soon as the action STEELE *v.* SAVORY was settled. Sir W. SAVORY, who was one of the members of the Council who met the deputation from the Association of Fellows in October, 1890, moved at the last meeting of the Council on March 10th: "That a committee be appointed to consider and report to the Council whether any, and if so what, further advantages can be extended to the Fellows." This proposition was seconded by Mr. MACNAMARA, and unanimously accepted. Thereupon Mr. WILLETT moved, and Mr. RIVINGTON seconded, a resolution to the effect that it is desirable to celebrate in some suitable manner the fiftieth anniversary of the institution of the Fellowship (the Charter creating this order being dated Sept. 14th, 1843), and that it be referred to the committee appointed under the preceding resolution to report on the best means of giving effect to this resolution. This proposal also was carried unanimously, and the committee appointed consisted of the President and two Vice-Presidents *ex officio*, Sir W. SAVORY, Bart., Messrs. CADGE, MACNAMARA, WILLETT, and RIVINGTON. As this committee comprises three members who belong to the Fellows' Association, there seems every prospect that the main principles for which the Association has been contending will soon receive official recognition. It must, however, be borne in mind that the cup may be dashed from the lip even in the very moment of triumph; and it will be as well for the Committee of the Fellows' Association to be ready to strengthen the case of the Fellows at a moment's notice. It is not difficult to suggest all kinds of technical difficulties in carrying out the simplest concession to the Fellows. What hindrances may not be conjured up to the provision of a common room

Digitized by Google

at the College, and how many more to consultation of the Fellows, and how many more again to the simplification of voting by voting papers and the election of the President by the Fellows! How easy is the utterance of *non possumus*, but everything that the Fellows desire will be possible if, like NAPOLEON, they decline to admit the existence of the word "impossible."

THE announcement made by Mr. RITCHIE in the House of Commons on Monday, the 14th inst., in regard to the new Royal Commission on Metropolitan Water-supply, is satisfactory in two respects. The scope of the inquiry is clearly defined, and, although it is not necessary to quote the instructions in full, our readers will see that the points referred to the Commission are precisely those which have been so often urged by ourselves. Before further legislation can be attempted it is necessary to know, first, whether the present sources of supply are sufficient for the requirements of London for some years to come; secondly, whether with scrupulous care the quality of this water-supply may be rendered safe even in times of epidemic; thirdly, whether increased demands on the other waters of the Thames and Lea will inflict injury on suburban districts; and, fourthly, if a distant source of supply is found to be necessary whether such supply can be obtained without injustice to provincial towns and centres.

The Commission appears, on the whole, to have been wisely chosen. In addition to two or three experienced officials, it includes the names of three well-known engineers, of Sir A. GEIKIE as a geologist, and of Professor DEWAR as a chemist. No exception can be taken to any of these gentlemen, and our only regret is that no trained bacteriologist is included.

That this is not the first inquiry of the kind is probably known to everyone, but no one who has not made a special study of the subject can have any idea of the enormous amount of research that has been devoted to it or of the mountain of Blue-books in which previous researches have been collected and fossilised. The history of the London water-supply, the complaints, inquiries, laws, and proposals in regard to it would, if told in detail, fill a large book, and the new Commissioners, instead of starting with a *tabula rasa*, will be embarrassed by the great mass of material they have to sift. A short and most imperfect sketch of the evidence already collected is all that is at present possible, but it will not be without interest, considering the magnitude of the question.

In the year 1581 PETER MORRYS, a Dutchman, obtained permission to supply a portion of London from the Thames by means of a water-wheel under one of the arches of London-bridge worked by pumps set in motion by the tide. For about 200 years a considerable supply was obtained in this way. Complaints, however, naturally arose in regard to such water, although there were then no drains to pollute the river with sewage, and accordingly in 1609 Sir HUGH MYDDELTON, with the assistance of a grant from King JAMES I., completed the great work which had previously been beyond his means, and the New River was opened to London. It need not be said that it has been a priceless boon to the metropolis. In 1691 the York Buildings Waterworks Company took water from the river near Charing-cross. This company was transferred to the New River Company in 1818, and the works were shortly afterwards abandoned. Following by a long interval the New River Company, the Chelsea Waterworks Company was started in 1723, and the Lambeth Company in 1785. The other London companies date from the earlier part of the present century. There are now eight water companies supplying London, of whom five draw their water exclusively from the Thames above Hampton, while two depend in part on the river Lea, and the last, the Kent Company, on deep chalk wells to the south of the Thames.

It is not surprising that, even in pre-sanitary times, complaints were made of water drawn and supplied without filtration from the tidal portions of the river. A Committee of the House of Commons sat in 1821; it, however, did nothing, and the complaints increased, and in 1828 another Committee of the House appointed the well-known Mr. TELFORD to inquire and report. The report was presented in 1834. Mr. TELFORD'S recommendations were impracticable, and then two more committees inquired but did nothing. In the meantime, in 1832, the cholera appeared in England. There was nothing to connect it with water-supply or drainage, and therefore its dread lesson was not learnt; but in 1849 another terrific visitation of cholera occurred. The deaths in 1832 are roughly estimated at about 5000, equal to 31·4 to 10,000 of the population. In 1849 the deaths amounted to 14,137, or 61·8 out of 10,000 people. By this time much human sewage went into the river, and so, unfiltered, into a portion of the water-supply, and subsequent investigations showed that the cholera explosion coincided pretty closely with the area of impure water-supply. Omitting several important inquiries, some of them instituted by the General Board of Health, which had recently been established, we come to 1852, when the Metropolis Water Act, which is still in force, was passed. This most valuable Act prohibited the companies from drawing any water from below Teddington Lock, and enforced filtration and the use of covered reservoirs. Shortly afterwards Dr. SNOW propounded the theory of water-carriage, which, although at first regarded as visionary, was by subsequent and bitter experience raised to the rank of a great sanitary law. In 1854 the cholera, to which sanitation is so deeply indebted, came once more, and 10,758 persons died in London, equal to 42·9 per 10,000. The water was better and the mortality less.

In 1866 the last, and we may hope the final, visitation of cholera took place. Thanks to Dr. SNOW and others the dangers of water pollution are now well recognised. The water-supply of London was far better, and the deaths in London, in spite of the greatly increased population, amounted to 5596 or 18·4 per 10,000. Of these a very large proportion occurred in an East-end district which was supplied for a time with water polluted by cholera poison.

The newly appointed Royal Commission, over which Lord BALFOUR of Burleigh is to preside, will be the fourth Commission of the kind, for we must exclude those bearing on the closely cognate subject of sewage disposal. The first was appointed in 1865. It issued three reports with important appendices, the last in 1867. It is known

Digitized by Google

as the first Rivers Pollution Commission, and its three double volumes deal with the Thames, the Lea, and the Aire and Calder. This was succeeded in 1868 by the second Rivers Pollution Commission, of which Dr. E. FRANKLAND was the presiding intelligence. The members of this Commission continued and greatly extended the work of their predecessors. They published six reports with many appendices, including maps and plans; the last, and much the most important, was the well-known Sixth Report, which appeared in 1874, in the form of a Blue-book containing 525 pages. This may be taken as the last public utterance on the great question. It is a monument of careful scientific study and reasoning. In 1867, a year before the appointment of the Second Rivers Pollution Commission, a Royal Commission on Water-supply was appointed under the presidency of the Duke of RICHMOND. Unfortunately, no chemist was nominated on this Commission, and the value of the conclusions arrived at are somewhat impaired by the omission. The report of this Commission, with two valuable appendices, appeared in 1869.

We must leave untold much that will be of vital importance in the labour of the new Commission. The Rivers Pollution Commissioners and the Commissioners on Water-supply differ diametrically from one another in their conclusions. Many schemes for future water-supply, some highly interesting, some absurd, were brought before each Commission and must now be reconsidered. Finally, bacteriology in its relation to disease has developed so rapidly in the last few years that it may almost be said to have been unknown in 1874, when the last great Blue-book was published.

MR F. W. LOWNDES, surgeon to the Liverpool police, has published in pamphlet form a paper[1] which he recently read at the Medical Institute of Liverpool, in which he sets forth from a medical standpoint some of the reasons why the office of coroner could better be filled by a member of the medical profession than by a solicitor or a barrister. There is much force in many of his arguments on the subject of this curious "survival of mediævalism," in respect of which "a general opinion prevails that much more security than exists for the election of suitable officials is needed." In ancient times the coroner was not thought to require special knowledge of either law or physic. He was a knight of the shire, who was "required to go upon information to the places where any be slain or suddenly dead, or wounded, and to summon four or five or six persons to aid him in inquiring when, and where, and how the deceased came to his or her death." Mr. LAWSON TAIT pointed out quite recently that the coroner's function as it exists now is "purely one of inquiry, the theory of which is that the inquiry shall be directed in all cases of death where the method of death is not clearly satisfactory." And *The Times* in like manner observes that "the operation of disease may be mysterious, or there may be reason to suspect violence. As soon as the coroner's court has ascertained the manner in which the fatal result was reached, its business is at an end." Mr. LOWNDES devotes himself to the question whether, in elucidating the mysteries of disease or the probabilities of violence, a knowledge of the laws which govern disease and health, and an intimacy with the modes of death, should not be the first essentials for adequate enlightenment. On the other hand, he asks whether familiarity with legal phrases and modes of detailing evidence should have the most weight, and if medical knowledge should be viewed as of secondary importance to an exact solution in a matter so restricted. Vague generalities, such as "found dead," "excessive drinking," "natural causes," and other equally unsatisfactory proofs of inability to state the true cause of death, need not entail much knowledge at all, either legal or medical; but neither can they be held to give an adequate verdict of the cause of death, which is the primary function of the court. He suggests that if every legal coroner had associated with him a medical assessor whom he would be bound to consult in every case where a discretionary power had to be exercised, the result would be different. Records of inquests held before the period of medical coroners are full of astonishing results arising from ignorance of the simplest medical facts on the part of coroners. In many a clear case of poisoning a verdict has been brought in and accepted by the coroner certifying that the deceased had "died by the visitation of GOD." From time to time incidents occurred which moved the tardy wheels of the Legislature in regard to this office, but the remedies were generally of a "meagre, miserable, and worthless character." The lack of medical evidence was deplorable, and the question of these "useless, expensive, and pernicious exhibitions" becoming one of national importance, a Select Committee of the House of Commons was appointed to inquire into the functions of the coroner. If it is urged that matters have become more satisfactory with advancing years, it is only necessary to refer to recent correspondence on the whole question.

Apart from these aspects of the subject, Mr. LOWNDES maintains that a medical man can administer the oath just as well as a barrister or solicitor, and looks upon the proceeding of "viewing the body" undertaken by persons who have had no previous medical training as a "farce." The object of this procedure is to obtain identification upon oath, and the due registration of all details, the latter especially when identification is impossible. The Bill to amend the Coroners Act of 1887, which Sir WALTER FOSTER has laid before Parliament, aims at dispossessing the jury of the function of viewing the body on which the inquest is to be held, unless the coroner or a majority of the jury should regard that procedure as essential. It may be readily questioned whether in the case of legal coroners their discretionary powers should be extended in this direction. Then there is the question whether a legal coroner is competent to decide the purely medical question of cause, in cases of sudden death, or of uncertified death, especially in those brought to his notice, but in which no inquest has, according to the exercise of his discretion, been deemed necessary. The ability of the medical coroner to obtain and deal with evidence has been frequently disputed by the members of the legal profession. Mr. LOWNDES answers the objection by remarking: "After

[1] "Reasons why the office of Coroner should be held by a Member of the Medical Profession," by F. W. Lowndes, M.R.C.S.Eng., surgeon to the Liverpool police.

Digitized by Google

years of medical practice, taking the evidence of witnesses in the Coroner's Court would be a very simple matter indeed." But, after all, it is necessary to grasp intelligently the meaning of evidence before it can be sifted. The medical witnesses are often embarrassed in giving evidence by having, as it were, to explain to the legal coroner the use of medical terms. Numberless instances of misconception might be recorded from the published reports of coroners' inquests. Dr. BENJAMIN WARD RICHARDSON refers to this. "For seven or eight years," he says, "I had much practice of this kind. There was at that time one of the most remarkable men in London as coroner for this district (the Central Middlesex)—Mr. WAKLEY,—a man of intense earnestness, force of character, indomitable courage, and sound freedom of expression in the views which he took. He was a medical coroner, and I remember well how very different a matter it was to give evidence before him compared with giving it before a coroner who knew nothing about medicine. It was simply impossible to make a mistake before Mr. WAKLEY, for there he was, ever ready to test the truth down to the bottom. If it came to be a question of chemistry, anatomy, or pathology Mr. WAKLEY was ready. The result was that never have the public interests been so well served as from the time when Mr. WAKLEY as a coroner took them in hand. It is natural that a witness should be more exact if he goes before a man who is a competent judge than if he goes before one who has no knowledge of the subject beyond the rest of the community."

Indeed, a great part of the lifework of the founder of THE LANCET was directed to effect reforms in the Coroner's Court which he held to be of supreme importance to the public interests. In the discharge of his duties he never failed to exercise his opportunities either as a coroner or as a Member of Parliament for the public benefit, and we notice that Mr. LOWNDES characterises as absurd the contention of those who consider that coroners and their inquests are superfluous, and should be ended instead of mended. In the hands of duly qualified coroners, that Court has been productive of much influence for good. To take only one example, the abolition of flogging in the army, and subsequently in the navy, can be traced back directly to vigorous action taken in the Coroner's Court. It cannot be too often reiterated that the abolition of this barbarity was due to the courage of the first medical coroner, already referred to, who, in spite of the most strenuous efforts made against him, fearlessly and determinedly overcame every obstacle, and exposed to the public in all its cruel reality the story of the unfortunate soldier who had been flogged to death at Hounslow. It seems to us unfortunate that of the 331 coroners in England only fifty-one have any medical qualification. The curiosities in the way of verdicts arising out of this condition of things are supplied by some 247 coroners having merely legal qualifications, and it has been for the last seventy years our frequently expressed opinion that the anomalies, too apparent and frequent in connexion with coroners' inquests, might to an enormous extent be prevented if purely legal knowledge were replaced by medical knowledge, and technicalities and subtleties gave place to accurate and intelligent comprehension of observed fact. This, however, will not be possible unless for the vacancies which occur suitable medical candidates are forthcoming.

THE Charter of the proposed Gresham University has been remitted by the Government to the Privy Council for reconsideration, and it is understood that this will result in the whole question of a Teaching University for London being again submitted to a Royal Commission. This means a delay of a twelvemonth or more. It is intended that this Commission shall be formed by such of the former Commissioners as choose to again serve on the inquiry, and of some three or four others, so as to make up the number to nine or ten. It seems quite certain that one or more of the former Commissioners will decline to serve, and the name of Lord SELBORNE, the chairman, has been included amongst these. This is much to be regretted, as his lordship is more familiar with the necessities of the higher education in London and of the peculiar position of our medical students than almost any other public man. He not only presided at the sittings of the former Commission, but drew up the main report, and he was also the most active member of the Select Committee of the Privy Council. The questions he put to the various counsel engaged by the numerous bodies interested in the problem amply showed how well versed he was in the subject, and how anxious he was to clear up and arrange the conflicting views put before the Committee. We can well understand that the abandonment by the Government of the judicial decision of the Privy Council drawn up by him and his colleagues is sufficient to cause his retirement from any further action in the matter, but his absence will in every way give cause for regret. The other members of the Royal Commission were Lord HANNEN, Vice-Chancellor Sir JOHN T. BALL, Sir WM. THOMSON (now Lord KELVIN), Sir G. G. STOKES, and Mr. J. G WELLDON. Lord SELBORNE, Lord HANNEN, and Vice-Chancellor BALL signed the report urging a reconstitution of the University of London, whilst the inability of that body to carry out such a reform, as was shown by the vote of the graduates in Convocation in May last, was accurately predicted by the three members who had had practical experience in university teaching. We would strongly urge upon the Government, when adding other members to the Commission, not merely the justice, but the absolute necessity, of nominating some member of our profession who is conversant with the needs of London medical education, and who may be relied on to investigate and clearly bring into prominence the disadvantages under which the London medical student is now placed, since the University of London only gives degrees on such onerous conditions as to constitute them really "honours" degrees, as declared by the former Commission. The existence of the Victoria University, and the freedom of its Colleges from the restrictions under which they laboured when affiliated only to the examining University of London, afford the clearest proof that there is a need of, and a precedent for, the establishment of a medical degree to rank between the London degree and an ordinary qualification, with which latter it is not proposed to interfere. The

Digitized by Google

opposition of the provincial schools of medicine was most ungracious and unwarranted, for the charge of an intention to lower degrees brought against the London teachers of medicine had been expressly and authoritatively refuted by their representatives again and again; but we are sure that another Royal Commission will only make it still more clear that to London medical students must be granted similar facilities for graduation as those existing at Manchester, Edinburgh, or Glasgow. Throughout the whole agitation in the press, at public meetings, and in Parliament the medical side of the question has received too little attention. We doubt whether the University of London, even though it may again make the attempt, can gather under its wing the various University Colleges in the provinces and in Wales, King's and University Colleges, unattached and collegiate students, and the London medical schools and those in the provinces, and mete out equal justice to its past graduates and to the future collegiate student in arts or science, much less in medicine. Its former scheme was the most unwieldy that could have gravely been put forward. The Gresham Charter presented a compact workable scheme, and, under a council composed of the various teachers as well as of the Crown nominees, would have done much to advance and consolidate medical teaching in London. We question very much whether the University of London can do a similar good service, whilst those who look to some great thing being the outcome of the Commission to be presently nominated will probably suffer much disappointment. The "democratic university of the future," and its establishment on a scale worthy of the metropolis, belong to the land where dreams are dreamed rather than to that which is guided by sober aspirations of practical teachers.

Annotations.

"Ne quid nimis."

THE IMPORTATION OF INFECTION BY SHIPPING.

AN important point has been raised by the Health and Sanitary Committees of the Corporation of Liverpool. It relates to the different procedures adopted under our present legislation with regard, on the one hand, to diseases the infection of which is practically endemic with us; and, on the other, to those, like cholera, which we deem to be of foreign origin. Small-pox, imported by vessels into the port of Liverpool, is allowed to spread, the sanitary authority getting little or no knowledge or power over it; and to this is attributed the fact that some forty cases of that disease are now under treatment in the corporation hospital. Then, again, it is pointed out that the distribution of authority in this country is most inconvenient, and calculated to prevent prompt action. Thus, when infection on board a vessel arriving in a port is in question, we have first the customs authorities and their powers; next comes the Privy Council, with their quarantine functions; then the Board of Trade are concerned; and lastly comes the Local Government Board, both as a central authority and as concerned with the administration of the Public Health Act by the local authority. The result is that Liverpool has decided to approach the Local Government Board on the basis of the following resolution:—"That the committee approve of the recommendation of the medical officer of health with reference to the more effective system of inspection of vessels coming into the port of Liverpool, and that the Local Government Board be respectfully requested to obtain such an alteration of the Quarantine Act as would transfer the power of dealing with all infectious disease on shipboard to the Local Government Board, and also to obtain an alteration of the Shipping Act relating to the passengers and the sanitary arrangements on shipboard." It must be admitted that our system for the sanitary control of vessels reaching our ports, and with regard to dealing with different diseases thus coming to our shores, is one that could never be defended if it were set out as a new scheme. It has grown up bit by bit, with increasing knowledge as to the necessity of preventive action; but early its stages preceded the formation of a public health department; and we now have to face the difficulty due to a number of departments dealing with the same or kindred subjects, and several of them clinging with tenacity to functions which they are ill-fitted to perform, but which must before very long be taken from them and amalgamated under one department. Whilst we would, for the present, avoid expressing any opinion as to whether increased powers should be given as to the control of individuals who are merely suspected of being bearers of infections that are current with us, we cordially agree in the main contention which Liverpool has embodied in the above-quoted resolution.

LIFE ASSURANCE AND DEATH CERTIFICATES.

A "Doctor of Medicine," upon whose letter to *The Times* we recently commented, writes us to reassert that he has good ground for saying that "there are members in our profession who would tone down death certificates." He does not, however, adduce any instances of the disgraceful conduct which in general terms he attributes to his professional brethren, and the only passage from experience which he gives us is the fact that he has himself been asked to examine for life assurance a patient who was suffering from cancer of the uterus. Our correspondent very properly refused to make the examination, knowing what he did know as to the condition of the person proposed for assurance, and he is not able to say what happened next. It is not necessary, therefore, to assume that the patient obtained a favourable medical report or a life assurance policy, or that any impropriety was committed by any person in this instance. We have the satisfaction of knowing that one medical man acted exactly as he ought to act in such circumstances, and we do not see any reason for making injurious assumptions about any others. While, therefore, we feel no doubt that a "doctor of medicine" is fully convinced that he has ample reason for the serious charges which he makes against his professional brethren, and while we quite agree with him that such conduct, if practised, should be strongly denounced and even severely punished, we must point out that it is the manifest culpability of such conduct which makes us loth to believe that it prevails in any part of the country. We, of course, do not pretend to believe in the probity and integrity of every man who holds a medical diploma. There are, as the old saying runs, "black sheep in every flock." But the charge, as we understand it, is that medical men in certain parts of the country are accustomed to fill up death certificates in such a way as to lend themselves to fraudulent life assurance. If that be so, the man who exposes the practice will be a public benefactor. But an accusation so terrible can only be made good by evidence precise, verifiable, and convincing. We cannot consent to take our opinions on such a matter at second-hand, even from the best informed and most judicious of our readers. A pseudonym which anybody in the kingdom might have assumed led us at first rather to suspect than

Digitized by Google

to believe the anonymous author of so odious a charge; and although we have now learnt, from a direct communication, and to our great regret, that the accusation is made by a member of our own profession, and one for whom we entertain a sincere respect, we must still decline, upon the grounds already indicated, to admit that a case has been made out. No man is entitled in such a matter to be judge and witness both. We shall hope that he is mistaken until convinced by evidence of the fact that he is correct.

ETHER AS A STIMULANT AT THE TEMPERANCE HOSPITAL.

IT will be seen that Dr. Ridge, in a letter which we print in another column, refutes the statements of the correspondent of a contemporary (the *Echo*) that ether is used at the Temperance Hospital instead of alcohol. We are much pleased to insert Dr. Ridge's letter, and not sorry that our allusion (which he calls a homily) to the subject has brought forth his reply. Whether our short notice of a serious public statement be a homily or not, his rejoinder certainly partakes of that character, if not of that of an actual sermon. We shall not follow him into all the various medical aspects of the alcohol question. He should know that THE LANCET is not insensible to the responsibility of practitioners who prescribe alcohol, or who give medical sanction to its use. It is a very frequent theme in these columns. We are not prepared to argue that alcohol, like ether in Ireland, should be scheduled as a poison. But we look confidently to the profession to sharply define its medical and dietetic uses, and by such definition to assist in the abatement of our greatest national vice.

ENTERIC FEVER AT TEMPLE CLOUD.

AN outbreak of enteric fever at Temple Cloud in the Clutton rural sanitary district is naturally causing local anxiety, because it is believed to be due to contamination of drinking water. The *Bristol Mercury* has done good service in bringing to light the facts with regard to this matter. One main source of water-supply is an old coal-pit; and such a source is known by experience to be in many instances a suspicious one. Then there are local private wells, some of which are referred to as indifferent in point of quality; and lastly, there is a tributary to the Cam which is also resorted to. The guardians of Clutton are guardians of health as well as of pauperism, and, notwithstanding this, it is stated that in their Poor-law capacity they allow the workhouse to pollute the Cam, which stream they, as a sanitary authority, ought to protect. This special pollution does not seem to have influenced the enteric fever at Temple Cloud; but its existence naturally lessens confidence in the local sanitary administration. Whatever be the cause of enteric fever at Temple Cloud, it is evidently a recurring one, and the least that the sanitary authority should do is at once to call upon their medical officer of health for a report on all the sources of water-supply which are resorted to in the village, together with an account of any means of contamination to which they run risk of being subjected. And if any such sources of contamination cannot with certainty be cut off or otherwise prevented, the authority having the duty of seeing that their district is throughout supplied with a wholesome water-supply should forthwith obtain advice as to an alternative service from an extraneous source. As the matter now stands, the circumstances are wellnigh unintelligible. The medical officer of health has reported on certain drain nuisances, but he significantly adds that the question of water-supply calls very strongly for the immediate attention of the sanitary authority. And yet, when the sanitary committee subsequently meet, they resolve that because the houses having either a deficient or an impure supply belong, with one or two exceptions, to the same owner, the question "does not require any interference on the part of the Parochial Sanitary Committee." What this means it is difficult to determine. Everyone knows that the Public Health Act distinctly refuses to admit that the responsibility of a sanitary authority is ever removed by delegation of duty to a parochial committee; and in the case of Temple Cloud this is fortunate, for this special parochial body is described as "almost defunct." One thing is certain, that the question of ownership of special cottages has nothing to do with the duty of the sanitary authority itself to perform its functions of protecting the public of their district from preventable disease, and o seeing that the inhabitants are provided with a proper water-supply. And it is this that should be definitely pressed upon them either locally or, if this fails, from without.

"VENICE IN LONDON."

IN special reports on the subject we have dwelt at length on the difficulties of warming and ventilating theatres and places of public assembly. It is no easy matter to enjoy an evening's entertainment without being exposed to foul air, overheating, or else violent draughts. For some time, however, Londoners have been able to avail themselves of at least one opportunity of witnessing a magnificent spectacular representation without incurring such inconveniences and risks. At Olympia there is such a vast expanse of space that it would be indeed difficult to befoul the atmosphere. The main building measures 500 ft. in length, 300 ft. in width, and 120 ft. in height, or a cubic capacity of 18,000,000 ft. The hall, it is true, can, it is stated, seat 10,000 persons; but, even in the extraordinary event of every seat being occupied, there would still be close upon two thousand cubic feet of air for each spectator, or about double as much as is generally considered necessary in a hospital. The problem, therefore, at Olympia is not that of giving sufficient air, but of maintaining the temperature of the air at a proper degree of warmth. The space is so great that the impression produced is that of an out-of-door entertainment. This agreeable result has been attained in a measure by warming the water of the canals. What we suppose may be called the lagoon in the main building and the canals in the reproduction of modern Venice present a surface of water measuring altogether a mile and a quarter. The Rosher system of hot piping is laid throughout the canals, and the water is thus warmed; but it took more than a week of continual firing to warm this immense bulk of water. There are altogether three million gallons of water, and, as it is necessarily shallow, the surface of evaporation is correspondingly large. The water, therefore, readily parts with its heat, and thus warms the building; but the process of warming the water has to be actively carried on day and night. The temperature of the water is never allowed to fall. Theoretically it is supposed to be kept at 60° F.; but during the recent extremely cold weather, when outside water was converted into ice, the temperature of the canals at Olympia has fallen as low as 54° F., and has seldom been above 57° F. A warming surface of a mile and a quarter has converted the icy air coming in from the outside into a soft atmosphere, in which the spectator can sit on the terraces of the cafés overlooking the canals, or watch the spectacular representation with ease and comfort, as if it were a summer's day. Here and there, in corners, where they are not readily observed, the hot-air pipes may be found outside the water. They then part with their heat directly to the atmosphere. Olympia, therefore, as a place of entertainment, offers

Digitized by Google

advantages similar to those of out-of-door pleasures, without the risk of the exposure to the rigour of our climate. The spectators may walk about or ride in the gondolas, stopping here to listen to the mandolin players or the melodious Italian singers, and there to watch the busy scene on the canals, where close upon a hundred gondolas flit about in every direction. The spectacular representation is one of the most gorgeous displays that has ever been presented to the London public. On the stage, which measures 300 ft. by 450 ft., 1400 persons appear simultaneously, without causing any sort of encumbrance, or in any way interfering with the atmospheric condition of the great hall. The large lake of warmed water between the stage and the spectators, and the distance of 120 ft. from the surface of the water to the roof above, constitutes a vast space where the air vitiated by the performers and the spectators is diluted and mixed with the unused supply. Thus an excellent entertainment can be enjoyed without any of the risks and inconveniences that mar the charm of even some of our best theatres.

A RIGOROUS EXPERIMENT.

INTERESTING and perhaps important in point of utility, an experiment lately carried out in the Russian army must come dangerously near to censure if tried in the light of humanitarian principles. In order to ascertain whether tents would suffice to shelter troops in the field during severe winter weather, eight soldiers chosen at random were, it is stated, made to pass the night, or as much of it as they could endure, under such conditions. Every care seems to have been taken to provide these men with warm and heavy clothing, and the snow within the tent was beaten down and covered with mats and straw. The men slept comfortably from nine in the evening until nearly four next morning, at which hour the thermometer showed that the temperature, originally registered as 31° F., had fallen to 4° below zero, within as well as outside the tent. Nature could then endure no more; sleep was impossible, and the soldiers only saved themselves from freezing by taking exercise in the open air. Everyone can understand the bearing of such observations on practical warfare, and we would not lightly disparage their useful intention. Nevertheless, it is something new to find the human species thus subjected to such an *experimentum in corpore vili*, and we sincerely hope that military necessity will not—as we believe it should not—call for its repetition. The recorded experience of arctic voyagers—who have often camped out in tents—may surely now suffice for evidence as to the amount and quality of clothing and of tent appliances required to withstand the extremes of winter cold.

THE DEBATE ON PHAGOCYTOSIS.

THE debate at the Pathological Society came to a close on Tuesday last, having thus occupied three evenings. It has certainly been of great value, and it says much for the skill with which it has been conducted that the interest in a subject which involves of necessity many points and arguments that are not easily grasped by the uninitiated should have been so well maintained. The paper with which Dr. Ruffer opened last Tuesday's proceedings was well worthy of the subject, and of one who is entitled to be regarded as perhaps the foremost student of phagocytosis in this country. It seemed to leave no debatable point untouched, and dealt in masterly fashion with the criticisms of Dr. Klein and the alternative hypothesis of Buchner and his followers. One great merit of this paper was the care with which its author avoided using the somewhat equivocal phraseology that has sprung up around this subject. There is no such thing, he boldly said, as "immunity" in the absolute sense, and throughout he preferred to speak of animals as being "naturally resistant" or "artificially protected," instead of using the hyperbolic terms that have become current. Phagocytosis, he maintained, is the only process which has been proved to be essential in the production of this resistance or protection, although "neither Metchnikoff nor any of his pupils has ever said that this was the *only* cause of natural or artificial resistance." Mr. Ballance's lucid exposition of the active part played by the fixed tissue cells in inflammation and repair and the subordinate *rôle* of leucocytes led up to the declaration that the former are probably the chief agents in phagocytosis; although the essentially chemical nature of the processes whereby immunity is secured was also pointed out. Mr. Hankin's interesting discovery of a proteid in the spleen of the white rat having bactericidal properties—although discounted by the supporters of the exclusive phagocytosis doctrine—undoubtedly gives strong support to the chemical theory of protection, and his speech was interesting as affording a reply to some of the arguments of Dr. Ruffer. In replying on the whole case, Dr. Sims Woodhead claimed that all the evidence hitherto adduced spoke in favour of phagocytosis being the agency at work in the living body, since the evidence on behalf of the humoralistic doctrine was derived from blood-serum or its products, which probably do not exist as such in the living animal. The summing up of Sir George Humphry was weighty and judicial, and his tribute to English bacteriologists was felt to be well deserved. The debate will, we doubt not, go far towards opening up new paths of research in this extremely interesting question.

RECOVERY OF MEDICAL CHARGES.

IT is always gratifying to report the success of a medical man in an action for recovering his charges. We have lately had occasion to notice the frequency with which such actions are rewarded by success. A case has just been reported in the *Sussex Daily News*, where, on March 8th, Dr. Whitmarsh of Brighton brought a claim against the Rev. J. Moses, rector of Itchingfield, for £25 odd for attendance on the defendant's wife and daughter. Medical particulars were not given. The defence was that the visits were too frequent and were over-charged. The defendant paid twelve guineas into court. The plaintiff, on the contrary, maintained that there was no excess of visits, and that the charges were reasonable. His Honour (Judge Martineau) said that, in regard to the number of visits, one must trust to the honour of the medical man. "If one thought that the doctor was making a job by running up the bill unnecessarily, the sooner one got rid of him the better." The jury found for the full amount, and expressed their belief that all the visits charged for were paid and that the charges were just.

MEDICAL LEGISLATION IN NEW SOUTH WALES.

THE Minister for Justice has introduced to the Legislative Assembly a Bill passed by the Legislative Council in 1890 to regulate the practice of medicine and surgery in New South Wales. The object of the Bill is to secure the registration of all regular practitioners possessing respectable diplomas, including those registered under the Imperial Act of 1886, or possessed of the degrees or diplomas of our examining bodies. The difficulty in such legislation is to deal with persons who have been practising for a certain time in the colony without diplomas. Great care is needed here, or the profession becomes identified with men who are sure to discredit it and to greatly injure the public. The following way of dealing with advertising quacks is somewhat original. The 17th clause is in these terms:—"Any person who shall advertise as treating disease, injury,

Digitized by Google

or ailment shall state his Christian and surname in full in the advertisement, and shall also place them upon any house or premises to which such advertisement refers, and, if not a medical practitioner, shall also add '*not registered under the Medical Act, 1890*,' in such manner as is prescribed by regulations. Any person who shall violate or neglect to comply with the requirements of this section shall be liable for every such offence, for every day he is guilty thereof, to a fine not exceeding £5; and any person, not being the person whose name appears in any such advertisement, who shall treat disease, injury, or ailment at any house specified in such advertisement, purporting to be the person whose name appears on such house or in such advertisement, shall be liable to a penalty not exceeding £25 for every such offence, and the proof of being such person shall lie on the defendant."

THE ROYAL BRITISH NURSES' ASSOCIATION.

WE publish on another page a letter from H.R.H. Princess Christian respecting this Association and its work which will attract great attention and awaken no small interest throughout the circle of our readers. The manner in which the endeavours of the founders of this society to create an organisation which shall consolidate and represent the profession of nursing in Great Britain have been beset and hampered by an interested opposition on the one hand and official perversity on the other is a very recent story, upon which we have been compelled from time to time to speak in terms other and stronger than we should have desired to use. But the difficulties so created have not daunted the promoters of the movement, who are entitled to the credit of having persevered with exemplary determination in the task to which they have set themselves. On the other hand, it cannot be doubted that the very sharp fire of criticism to which the scheme has been subjected has enabled its framers to perfect its details, as they probably could not have done without this assistance, although the tone and manner of the criticism have absolved them from any oppressive sense of gratitude to their critics. The result of this not too genial coöperation is before our readers in the abstract of the Draft Charter, which we publish on another page. From that abstract it will be seen that H.R.H. the President is supported by a distinguished body of corporators, whose eminence cannot fail to satisfy the Privy Council that the scheme commands the cordial support of at least a fully representative body of medical men and nursing authorities. If it should be necessary to renew at Whitehall the discussion which has been carried on in the press and elsewhere ever since the initiation of the movement, we do not doubt that the promoters, who have had much the best of the argument throughout, will be able to satisfy the committee, which is at least too familiar with legal procedure to adjudicate upon a claim without hearing in its support those who advance it.

THE MEDICAL MISSIONARY.

THE Edinburgh Medical Missionary Society has just celebrated its jubilee, and in the speeches delivered on the occasion the amplest evidence was adduced of the success with which it has been worked, and of the yet greater future in store for it. History repeats itself, and the medical scholar will note the fact that, while the healing art had its first beginnings under the fostering care of the priesthood, it has returned, in one important field of its exercise, to its early alliance with religion. Returned, we say, but with a difference, for while in ancient India and China medicine was made the instrument of a degrading superstition, it has nowadays become in those very regions the handmaid of a civilising faith; the two professions, that of practitioner and preacher, coöperating duly each in its proper sphere, for the rehabilitation of a morally and intellectually impoverished humanity. In the first quarter of the present century religion and medicine had no grander representatives than Dr. Chalmers, on the one hand, and Drs. Abercromby and Alison on the other—the men at whose instance the Edinburgh Medical Missionary Society sprang into life. Every decade that has since elapsed has witnessed an advance both in the theological and the medical qualifications of its votaries, till it attracts to its service young men combining in both capacities a professional efficiency unsurpassed by their home-placed contemporaries in either. Dr. Martyn Clark was able to draw on his great Indian experience in proof of this position, insisting as he did on the necessity of exacting from the medical missionary a standard of excellence in his twofold activity not inferior to that of his single-handed brethren of the Motherland. Already, as the literature of the profession can testify, the resources of the healing art have been enriched by medical missionary labour and experience; while an interesting paper might be written on the peculiar advantages possessed in the field of territorial exploration by pioneers who have combined with the religious impulse the accomplishments and the spirit of the surgeon and physician. Names like those of Mungo Park and Livingstone rise at once to the memory; and among German and Italian explorers of more recent date the twofold coincidence receives yet fuller illustration. At the meeting in Edinburgh on Monday last Mrs. Bishop, herself a traveller of distinction, pointed out the vast field yet to be covered by such societies, whose emissaries are everywhere "the object of love and trust, everywhere offering in themselves the best interpretation of the Christian law of love." Great Britain is the most successful of colonising Powers. The rapid development of her medical missionary societies is the most effective proof that, in the highest of all respects that success is merited, and will be more than maintained.

FAT EMBOLISM.

DR. W. F. WHITNEY contributes a paper on this subject to the *Boston Medical and Surgical Journal*, Feb. 18th, 1892. He relates the case of a man, aged sixty-two, who sustained a fracture of the right femur by the falling of a life. Nothing unusual was noticed until the middle of the third day, when vomiting commenced, and fluid collected in the abdominal cavity. The patient died on the fourth day. At the necropsy the vessels of the lungs were found to be extensively plugged with fat; the head was not opened, and all the other organs were healthy. Dr. Whitney reviews some of the work which has already been done on the subject. Majendie, in 1827, was the first to prove experimentally that oil injected into the veins of an animal would produce death. But it was not until 1862 that Zenker called attention to the presence of fat in the vessels of the lungs in some cases of death after fracture of the leg, and it then came to be regarded as sufficient to account for the fatal issue. "But gradually, as the infective processes with which it was often associated were better understood, the conviction grew that fat embolism of the lungs alone was not sufficient to produce death, and that its action on centres more remote must be considered. By far the most thorough and exhaustive study was made by Scriba in 1879, and since then but little has been added to our knowledge. The problems which he proposed were: 1. How much fat is required to kill? 2 In what way does it act? 3. How is it eliminated? In answer to the first question he found that in order to kill an animal by fat embolism a quantity is necessary varying with the force with which it is injected and with the distance of the point of injection from the heart. But in

Digitized by Google

no case was it less than three times the amount of fat contained in the entire femur of the animal. His conclusion as to the mode of action is that death after aseptic fat emboli occurs only from large numbers of them in the brain and spinal cord, and in consequence of the arterial anæmia and the resulting disturbance of nutrition." He further showed that the oil has no action on the heart, and that in regard to the lungs, five-sixths of the arteries must be tied before an animal is killed, and that therefore there is never such a degree of embolism of the lung capillaries that death must result. On the other hand, it is the fat which has passed the lungs and reached the central nervous system that is the cause of death. In answer to the third question, his experiments and clinical evidence point to the kidneys as the organs by which the greater part is eliminated. A smaller part is undoubtedly burned up in the system. Of the symptoms noted, one of the most striking was the constant fall in temperature. Another symptom was dyspnœa, due to the loss of oxidation of the blood; this was often only transitory. Slight hæmoptysis, due to infarction, has also been noticed. The most important clinical symptom of fat embolism is the presence of oil in the urine. Scriba sought this in a number of patients suffering from fractures, and was able in nearly all the cases to demonstrate it to a greater or less degree. The fat could not be recognised as such by the eye alone, but with the microscope there were seen numerous very small, round drops, which were highly refracting, and had a fine dark border. The elimination was not continuous, but interrupted. A marked pallor of the skin and mucous membranes was noticed in all the animals experimented on.

DEATH OF DR. C. MEYMOTT TIDY.

WE regret to have to announce the death of Dr. Charles Meymott Tidy. Dr. Tidy last year suffered from an attack of influenza which left him much impaired in strength, flesh, and colour. He seems never fully to have recovered, and for the last few months he has been much hindered in the discharge of his multifarious duties. He was Professor of Chemistry, Medical Jurisprudence, and Public Health at the London Hospital, the official analyst to the Home Office, and medical officer of health for Islington. He wrote many works on legal medicine, and was the author, conjointly with Dr. Woodman, of a "Handy Book of Forensic Medicine and Toxicology." He had for some time assisted in drawing up the monthly and annual reports on the quality of the water supplied to London. He graduated with the highest honours in Aberdeen University, was a Member of the Royal College of Surgeons, and a Licentiate of the Society of Apothecaries. He was also a barrister at law. His position was due to no accident of birth or education, but was the result of inherent ability and indefatigable work.

THE NOTIFICATION OF MEASLES.

AT a recent meeting of the Public Health Committee of Cork a forcible letter from Mr. Donovan, the superintendent medical officer of health, was read, arguing the unreasonableness of leaving out measles from the list of notifiable diseases under the Notification Act. Mr. Donovan pointed out how much more fatal it is than the diseases whose notification is specified in the Act. Thus in the three years 1886, 1887, and 1888 the deaths from erysipelas, simple fever, and measles were respectively 1, 2, and 159. From the comparative abeyance of measles in recent years, except 1887-8, he estimates a large number of children to be liable to the disease, which is already showing itself in different parts of the city. He is strongly of opinion that the early notification of cases would tend greatly to prevent an epidemic. The absence of measles from the notification list is the more marked as it used to be notified before the Act. These obvious and weighty considerations prevailed with the committee, which, on the motion of Mr. Atkins, took steps to have measles included in the Notification Act. We may expect this course to be followed by all sanitary authorities who are not penny wise and pound foolish. Some authorities are concerned at the fact of having to pay for the notification of measles. At Kidderminster, where the authorities had received notification of ninety-five cases of measles since Feb. 1st, one gentleman complained of the cost as a perfect waste of money. In moving the adoption of the Health Committee's report Mr. Parry complained that they did not receive from some medical men all the help they might expect, and seemed especially displeased with one gentleman who very properly apprised the Committee of a recent decision—Chisholm *v.* Radcliffe Local Board—that medical men notifying cases were entitled to the full fee *without deduction for postage*. It will be unworthy if the authorities show any illiberality towards medical men doing their duty. On the contrary, they should reward early notification by generous admission of its utility, if not by extra pay. They should allow, too, for the difficulties of notification, arising from difficulties of diagnosis, which are felt by all but the ignorant.

THE REPORT ON PERFECT COMBUSTION AND SMOKE PREVENTION.

WE have received a very lengthy communication from Mr. J. Knapton Thompson, C.E., of Leeds, claiming that a portion of the construction of Leggott and Marsh's patent fire-range violates an invention and patent of Mr. J. Knapton Thompson in, as he alleges, two most important particulars. It is obvious that we cannot decide between the rights of the respective parties, nor have we room in our columns for such a discussion. We simply described the fire-range as we found it.

A NEW BOMBAY VACCINATION BILL.

THE *Times of India* contains a very interesting report of a meeting of the Council of the Governor of Bombay for the purpose of hearing the second reading of a Bill to prohibit the practice of inoculation, and to make the vaccination of children in certain parts of the Presidency compulsory. The meeting was addressed at great length by the Hon. Mr. Javerilal W. Yajnik, the Hon. Mr. Rao Bahadoor, Mr. G. Ranade, the Hon. Mr. N. N. Wadia, the Hon. Mr. J. R. Naylor, and others. The second reading was moved by the Right Hon. Sir Charles Pritchard. Vaccination has been compulsory in Bombay since 1877. The purpose of the present Bill is to extend the law to other parts of the Presidency. The discussion was very creditable to the intelligence of the Council, not least to its native members. The chief feature of the Bill is that it enjoins compulsory vaccination with calf lymph whenever the parent or guardian of the child shall so require. Practically all the speakers recognised the benevolence of this law, and agreed to the principle. The only subject on which any material difference arose was contained in certain words in Section 14, giving the Governor in Council power to sanction vaccination with human lymph in cases of emergency and where delay would be dangerous. His Excellency the Governor heard objections stated at great length and certainly with much ability. But finally the Bill was read a second time on the understanding that the time for the statement of such objections was in committee. The objection is based not only on the ground that disease, such as syphilis or leprosy, might be conveyed through vaccination, but that considerations of caste might be offended by vaccination from those of inferior caste. Mr. Naylor spoke with great force in defence of the Bill as

Digitized by Google

it stands, and made a statement to the following effect: "No case that I have ever heard of in India has been brought forward as a proof that the employment of human lymph is dangerous to the health and life of the child. I have now had pretty nearly thirty years' experience of the Mofussil, and in the course of my duties have come across Indian gentlemen of all classes, and I cannot recall an instance in which I have ever had brought to me a single complaint against the use of human lymph." We commend this statement to anti-vaccinationists at home, and the fact that the principle of compulsory vaccination is recognised by all classes and creeds in Bombay as a law of benevolence and wisdom. We think the Government are right in reserving to themselves power to use human lymph in emergencies. The supply of calf lymph is practically capable of great extension, but in the case of outbreaks in outlying districts it would be absurd to hesitate in the use of arm-to-arm vaccination where animal lymph was not at hand. Arm-to-arm vaccination is still practised in England, though there is an increasing disposition to supply the alternative of calf lymph.

THE ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

EPSOM COLLEGE is an institution not unknown to our readers, and one the claims of which have on many occasions been advocated in these columns. The appeal which we print to-day from the chairman of the Council and other representative officers of the institution brings the matter afresh to the notice of the profession under a new aspect; but the position is by no means hard to understand. The work of the College is twofold. It affords a retreat to a certain number of poor and incapacitated medical men or their widows during the declining years of life. It also provides a first-class education for some 600 boys, among them being foundationers. At present these two departments are carried on under one roof, and the arrangement, not an ideal one at best, has become exceedingly inconvenient by reason chiefly of the growth of the school, which demands more space than is afforded by the accommodation at present assigned to it. Hence the Council propose to send the pensioners home to their friends and convert the premises at present occupied by them to educational purposes. It is, however, impossible to carry out this plan without providing the pensioners with such allowances as will enable them to live elsewhere. The dwelling accommodation which they at present enjoy free of cost is a large part of their allowance, and if this be withdrawn it must be compensated for by an additional pension granted in lieu of it. To provide such additional pensions the Council are appealing for a capital sum of £26,000, in furtherance of which object the Lord Mayor of London has consented to preside at the biennial festival of the College on the 5th proximo. The cause is one which does not need to be supported by eloquent or ingenious pleas; to state the facts is to plead the cause, and we hope that the timely notice of the festival now given will secure a large attendance, in which case we have no doubt that the necessities of the College will evoke a generous response.

ARMY RECRUITING.

LIEUTENANT GENERAL FIELDING, the Inspector General of Recruiting, has just issued his yearly report. He states that the total number of recruits that joined the regular army during 1891 was a little over 36,000. Of these, there were 12 975 specially enlisted, either on account of their not being up to the required standards or because of the regiments selected by them being closed for recruiting. We have not space to go into the details connected with these figures and the inspector-general's remarks as to the medical examination and the chief causes of rejection, nor can we discuss those sections of the report dealing with the waste of the army and the army reserve. As regards the militia, out of 37,487 recruits enlisted only 34,983 were finally approved and came up for preliminary drill. General Fielding's report refers to the depopulation of rural districts and the increase of towns, the comparative failure of Ireland as a recruiting ground, and other things as seriously affecting recruiting. That the returns for each year show a steady decrease of crime of all sorts in the army is a satisfactory and well-known fact. After due consideration of the subject from every point of view, and in face of the necessity to provide over 39,000 recruits during the present year, General Fielding cannot do otherwise than recommend that no change be made in the standards of age, height, weight, or chest expansion, and in the permission to enlist lads of eighteen and upwards who appear likely to develop into efficient soldiers. With the continuance of these regulations he does not apprehend that any well-founded ground for complaint will arise as to the ultimate fitness of most recruits for the career of a soldier.

THE COUNTY COUNCIL.

WE observe with much satisfaction that the London County Council has elected amongst its aldermen Sir John Lubbock, Mr. Beachcroft, and Mr. Hoare. Sir John Lubbock occupies so high a position among thinking men that his association with the London County Council will materially strengthen it. Both Mr. Beachcroft and Mr. Hoare have done excellent work on the Housing of the Working Classes Committee, and it may be anticipated they will take prominent positions on the Public Health Committee which will shortly be constituted.

"ELIMINATION OF MICRO-ORGANISMS BY THE SWEAT."

UNDER the above title a short paper appears in *L'Union Médicale* for March 3rd of this year. It commences by stating that it is still an unsettled question as to whether micro-organisms are able to pass through certain vessels and organs, and then be eliminated by means of the kidneys or intestinal canal, when these organs are in themselves perfectly unaffected and in a healthy condition. According to some authorities, amongst whom is Wyssokowitch, such an event can only occur when there is a sanguineous exudation, or the tissues of the kidneys or intestine are diseased. Some observers, on the other hand, deny that such conditions are necessary. Thus Trambusti and Maffucci maintain that they have found anthrax bacilli in the urine and bile when no disease whatever could be found in the kidneys and liver. Baumgarten, again, states that he has seen tubercle bacilli pass from the blood into the tissues when the walls of the vessels were quite healthy. From other authorities we learn, on well-established evidence, that pathogenic micro-organisms can pass into the milk when the mammary glands are unaffected. Brunner[1] investigated this matter from another side, and demonstrated the fact that pathogenic microbes could be eliminated by means of the sweat. This investigation was met with a great difficulty from the outset—namely, that it was not easy to sterilise the skin so as to be sure that the micro-organisms which were found in the secretion, and cultivated in artificial media, were derived from the tissues and fluids of the body, and not from its cutaneous surface. This difficulty was overcome by using animals for experiment which had been inoculated with disease, the pathogenic organism of which could not accidentally have found its way on to the skin. The animal was then made to perspire profusely by artificial means, pilocarpine being usually employed for this purpose, and then

[1] Berlin. Klin. Wochenschrift, May 25th, 1891.

Digitized by Google

further inoculation and cultivation experiments were made with the sweat. Proceeding in this way, Brunner injected a culture of staphylococcus aureus into a hog, one of anthrax into a cat, and one of micrococcus prodigiosus into a sucking-pig. In all three cases the microbes injected were found in the sweat, and also in the saliva. This is an important discovery, from both practical and theoretical points of view. It gives to crises, accompanied by profuse perspirations, which may be produced artificially or occur naturally, a still more important place than they formerly held. It also demonstrates that there may be great danger in allowing a patient who has been sweating profusely to possibly reabsorb the secretion, and that therefore it is a good plan to employ moderate friction with dry cloths when such a crisis occurs, and to subject all linen and clothing capable of absorbing the sweat to immediate disinfection. Another precaution which the investigation indicates is that when an abscess is discharging externally, or when a patient is suffering from erysipelas or other infectious cutaneous affection, there is great danger to the patient himself if the linen &c. are not changed after profuse sweats, as the micro-organisms may possibly be absorbed by the skin. It is singular, however, that several observers (including Mattei, Surmont, and Lille) have failed, after numerous attempts, to find tubercle bacilli in the sweat of phthisical patients; so numerous have such trials been that we may almost consider it as absolutely proved that such migration of the bacilli does not occur.

A MEDICAL CENTENARIAN.

IN a morning contemporary of the 16th inst. is published the following paragraph: "Mr. William Salmon of Penllyne Court, Glamorganshire, who was born in the parish of Wickham Market, Suffolk, on March 16th, 1790, completes his 102nd year to-day. He is supposed to be the oldest living Freemason, and the oldest member of the Royal College of Surgeons." On reference to the College Calendar we find the name of William Salmon under the date 1809, in which year Thomas Keate was "Master" (there were no "Presidents" in those days). Mr. Salmon was perhaps examined by Everard Home (the first "President" and the brother-in-law and executor of John Hunter), whose name appears in the "Court of Examiners" for 1809. John Hunter died in 1793, so that there is still living a member of the profession who was born before the great surgeon's death the centenary of which is fast approaching. Truly, Mr. Salmon is a most interesting link with past professional history. Would it not be a graceful act on the part of the Council to confer honorary distinction on their venerable "Member"?

THE CLEANSING OF WOOD PAVEMENT.

No one who has lived in a city during recent years will dispute the fact that wood pavement now in such common use, notwithstanding the comparative ease and quiet it has introduced into the course of traffic, is open to at least one permanent objection. It is, in consequence of its comparatively non-absorbent composition, essentially dusty, and the dried mire and refuse of the thoroughfare, not wholly removed by the boys with brush and shovel, is blown here and there, and is a cause of annoyance to the olfactory sense and the air-passages of any persons whose perceptions have not been quite blunted by its repeated irritation. We might speak, too, of possible risks of contagion. Germs in endless variety may be looked for among its particles, and if we are happily not ourselves conscious of their mischievous influence we may attribute this, not to their assumed absence, but rather to personal immunity, or more probably to the attenuating influence of surrounding air and sunlight. If we ask by what means this chronic inconvenience may best be remedied, one principal agent, water, however applied, seems alone to promise an effective result. It has been suggested that the watering cart now in use for this purpose were best superseded by a hose worked often and regularly upon all roadways paved with wood. The suggestion is a good one. It would, however, we fear, prove expensive both as regards the supply of apparatus and of labour. The same end would be served, and probably at a less cost, by supplementing the existing agency of water carts by means of a roller brush like that used in clearing tramway lines. Whatever the method employed, it behoves local authorities to give the matter their early consideration. Should we be favoured with a period of dry, mild weather after the recent snow, frost, and rain, we need have no doubt that March winds will early remind us, whether in town or country, of the discomforts of the dusty highway.

NEURITIS FROM EXPOSURE.

IN the new *International Medical Magazine* Dr. G. W. McCaskey utters a word of warning with regard to the early recognition and treatment of the simpler forms of nerve inflammation. Many of these, he says, are first regarded as cases of rheumatism or neuralgia until a subacute or chronic stage has been reached, at which the condition is very intractable. To assist in making the diagnosis he emphasises the importance of discovering whether there is tenderness in the nerve trunks as well as of attending to the etiological factors in the condition. Amongst these exposure is conspicuous, and continuous pressure is also to be kept in mind as a not uncommon cause. With regard to treatment, absolute rest is insisted upon. Even the hand, if the arm is affected, must be rendered immobile, and the limb should be placed in the posture which exposes the nerve trunks to least tension. The free use of hot compresses to the limb is also recommended, but in the early stage the beneficial effects of electricity in any form are somewhat doubtful. A compress, however, as hot as it can be borne, usually secures marked relief from pain, and allows morphia to be for the most part dispensed with; and after the acute symptoms have subsided the use of a weak galvanic current—whether ascending or descending is of little consequence—is strongly recommended.

THE VENTILATION OF COW BYRES AND TUBERCLE.

ANYTHING bearing upon public health which comes from the pen of Dr. J. B. Russell is always worth careful perusal, but he has seldom set forth more important considerations than those which he has included in a memorandum in which he points to the need of some modification in the existing system for the licensing of cow-byres in Glasgow; his object being to secure that such questions as the ventilation and the cubic capacity to be required in cowsheds shall be controlled by the sanitary authority. Throughout he holds in view the danger which the public run of contracting tuberculosis through the agency of cow's milk, and in considering, in the first instance, the necessity for maintaining the health of the cows themselves, he quotes Professor MacFadyean to the effect that "there is not a single known fact in connexion with physiology to lead us to believe that those animals are any more resistant to the prejudicial influence of the effete matters they add to the atmosphere than human beings are." He then recalls the fact that the Army Regulations require 1600 cubic feet for each horse, and that in the army horse-infirmaries 1900 are insisted on; and he again quotes Professor MacFadyean, who says that "probably a suitable cubic capacity would be, for a cow or other full-grown bovine, 1200 cubic feet." But when we come to compare

Digitized by Google

horses and milch cows, we must remember that the health of man is directly concerned in the latter, whereas the health of horses has no such bearing. And, further, the horse is not exposed to any such exhausting process as an artificially induced excessive lactation, so that whatever is needed to maintain a horse in reasonable health can hardly be deemed excessive in the case of a cow supplying milk for human consumption. Having regard to all these considerations, it is somewhat startling to find that in Glasgow the prescribed space for the town-stalled cow is only 400 cubic feet, that in Kilmarnock the same has hitherto been allowed, and that in Oldham as few as 350 cubic feet have been sanctioned. Kilmarnock now makes a slight advance to 500 and Oldham to 600 cubic feet. The majority of towns from which information could be obtained require some 800 cubic feet, and the Local Government Board have also advocated that as a minimum standard. According to recent experience, such a standard cannot be regarded as excessive; and, if health alone had to be considered, it must necessarily be regarded as falling short of that which ought to be provided in the case of milch cows, whether in town or in country places. The main objection raised against a healthy standard has been the contention that warmth is necessary to maintain the flow of milk. But, as Dr. Russell asks, is this warmth to be the heat of the cow herself, preserved by enclosing her in an atmosphere loaded with impurities from her own pulmonary, cutaneous, and intestinal excretions? He definitely states that no conditions could well have been more surely devised for the cultivation of the bacillus of tubercle than those of a cow drained by the forced secretion of her milk, living in an atmosphere heated by her own body, and loaded with her own organic impurities. A free flow of milk from tuberculous cows is, in the first instance at least, profitable to the farmer; but, quite apart from the danger which it involves to our milk-fed children, it surely cannot, in the end, pay the farmer to produce tuberculous cows by such means as have hitherto been so common, and such as Dr. Russell so graphically describes. The cry of farmers is for compensation in the case of cows found to be tuberculous, and this cry has in the main led to the Royal Commission on Tuberculosis. But surely, so long as there is any chance of profit as the result of keeping cows under conditions which must certainly tend to tubercle, the case can hardly be one for compensation to the owners of these cows. Dr. Russell's memorandum, which is primarily addressed to his own authority, deserves the serious consideration of all sanitary authorities and dairy farmers; and so long as such conditions obtain as he describes, so long will it be important for parents and householders to boil or otherwise cook all milk used for the purposes of human consumption.

CHOLERA OCCURRENCES.

IN Syria the villayets of Aleppo and of Damascus have now remained free from cholera since early in January; and in Beyrouth the disease would seem to have almost disappeared, a few mild or suspicious attacks alone having occurred at Halessa and the immediate neighbourhood of that place. The Hedjaz is also free; Yemen district is, however, still looked upon as "suspect," although no definite occurrences of cholera would appear to havebeen reported thence. The cholera epidemic in Japan caused 4020 deaths in 1891. This is much less than in 1890, when 31,463 fatal cases were recorded. It is also to be hoped that the 1891 outbreak closed the epidemic period, for no fatalities were recorded during the month of December. From Teheran comes recent intelligence to the effect that cholera is widely prevalent amongst the inhabitants of Herat, and that the disease is extending. Within the last two years we have had repeated information as to cholera in Persia, but it was mainly towards the western portion of that empire, and in connexion with the epidemic in Mesopotamia; but this by no means implies that the disease at Herat has not been imported owing to unreported occurrences of cholera in Persia. Herat lies some fifty miles beyond the western boundary of Persia, and at the present moment the disease is stated to be spreading eastwards towards and across the Perso-Afghan frontier, along the main road from Herat to Meshed; Kuh-Sam, the last Afghan town in the direction of the frontier, is already attacked. Russia is taking special precautions against the spread of the disease from Afghanistan into Russian territory.

PARLIAMENTARY MATTERS.

MR PEASE has procured from Mr. Balfour the consent of the Government to a Select Committee on the registration of midwives. This is undoubtedly the way in which to settle this vexed question, and to give a fair hearing to all opinions. It may be questioned, however, whether Mr. Pease would not have shown more discretion in waiting for a new Parliament. Members are thinking now of little but their constituencies. Dr. Cameron hopes to induce the Government to order more perfect returns from the authorities of churchyards and cemeteries as to the number of burials of stillborn children. With regard to the present position and prospects of the Gresham University and the action of the Government in regard to it, we may refer our readers to a leading article in our present issue.

EFFECT OF DEEP INSPIRATION ON THE ASSIMILATION OF FAT.

ACTING on Professor Chudnovski's advice, Dr. A. Pavpertoff has made a series of observations on the effect of deep or forced inspiration and expiration on the assimilation of the fatty matters contained in food. The observations were made on nine healthy young persons, some of them being carried out in winter, others in summer. The sittings were held once a day in a large and well-ventilated room, each subject making from 120 to 200 forced inspirations and expirations. By analyses of the fæces during the three periods—before, during, and after the forced inspirations—it was found that the amount of fatty acids in the fæces in all cases diminished during the second period, the average diminution being 1·246 per cent. In the third period the quantity of fatty acids, as compared with that excreted in the first, diminished slightly in some cases and increased slightly in others. All that can be stated therefore as the result of the experiments is that a slight increase in the assimilation of fat takes place while forced or deep respiration is going on. The above research is published as a "preliminary note" in the *Vrach*, No. 6, 1892.

INTRA-CRANIAL SURGERY IN ITALY.

IT is cheering to witness the advance of surgery in Italy, which now bids fair to resuscitate the best traditions of Fallopio, Tagliacozzi, and Scarpa. Intra-thoracic and intra-abdominal surgery owe not a little to her recent operators, prominent among whom may be mentioned poor Count Loreta of Bologna, whose tragic end on July 23rd, 1889, as described in THE LANCET of Aug. 3rd following, is one of the saddest pages in the annals of the profession. His resection of the liver, and, still more, his digital divulsion of the œsophageal and pyloric orifices of the stomach, did not require the commemorative tablets in the Bologna Hospital and University to perpetuate their author's pre-eminence among his contemporaries. His influence and teaching are still active for good in the direction which would have pleased him most—that of intra-cranial surgery. In Florence, the week ending March 12th has been

Digitized by Google

signalised by a brilliantly successful operation in this department. Professor Baiardi, of the Spedale della Maternità there, had under his charge in the children's ward a little boy of four years and two months, suffering from "general cortical epilepsy," according to the official bulletin, "and idiocy." Having trepanned the cranium, Professor Baiardi (assisted by Drs. Mattucci and Giarré) removed two great tracts of bone in the parietal regions, "in correspondence with the *zona motrix* of the cerebellum." From the first day after the operation the little patient's eye, nearly always wandering, uncertain, and unconscious, "si mostrò sereno ed animato da un lampo di intelligenza" (showed itself serene and enlivened by a flash of intelligence), the "habitual restlessness was replaced by calm," and "sleep came to restore the feeble limbs of the child, which, a prey to sickness at the threshold of life, had neither consciousness nor instinct, could neither speak, nor walk, nor indicate its bodily requirements in any way; did not even know how to masticate." The recovery, vigilantly watched and assisted, is already so far satisfactory as to warrant every confidence in the lasting success of Professor Baiardi's operation.

THE ROYAL COMMISSION ON VACCINATION.

THE question which was recently addressed to the President of the Local Government Board as to the date when the Royal Commission might be expected to report affords an indication of an impatience which is not without justification. The Commission has already sat for nearly three years, and still sits weekly. The Commissioners began taking evidence under their third heading: "The case against vaccination, and especially against its continuing to be made compulsory," on Dec. 4th, 1889, and witnesses to the same effect have since then almost continuously occupied their time. We have no desire that any improper curtailment of evidence under this heading should be made; indeed, some of the most verbose witnesses whose evidence has as yet been published have rather helped than hindered the cause of vaccination. But we do hope that some limit will be put to mere verbiage, whether coming from one or the other side, and that the essential points on which the public desire authoritative guidance will not be lost amid a mass of unintelligible and irrelevant material, such as is regarded by some people as constituting "evidence."

REPORTED INFLUENZA AT NICE.

THE reports circulated in some portions of the daily press concerning the prevalence of influenza at Nice and in the Riviera generally, and the large exodus of visitors from that favoured resort, appear to be greatly exaggerated. A correspondent at Nice informs us by telegram that though influenza has been present there since November, the cases have at no time been numerous, and the mortality-rate has been small. The disease has now almost disappeared, and the health of the town is unusually good.

THE SLIPPERY STREETS.

THE unusual, and so far unseasonable, phenomenon of continued frost which has distinguished the present month has been comparatively free from some of its most familiar disadvantages. It has attained to no extreme severity, has not gravely affected public health, or occasioned a water drought with all its present and subsequent inconveniences. One inseparable drawback, the slippery street, is, however, of too near and pressing importance to be overlooked, and we are not, therefore, surprised that this has been duly marked for amendment in the daily press. Attention has been drawn to the perilous labour of overweighted horses as they struggle to make their uncertain way along our chief thoroughfares, guiltless as many of these are of any reliable attempt to provide a secure foothold. Ashes and sand may be had in abundance, and are even stored, evidently for use, at central points of traffic; yet there is lacking the intelligent energy required to utilise them. The matter clearly calls for inquiry on the part of civic authorities, and we trust that, should the present thaw prove to be of a transient character, the doorstep, the pavement, and the roadway, alike well dusted over, will bear witness to the prudent sense of those whose care they are. At least this much is due to the safety of man and beast.

DIPHTHERIA IN THE NEWBOTTLE DISTRICT.

DIPHTHERIA, evidently of a very infectious character, is prevailing around Newbottle and New Harrington in the Houghton-le-Spring rural district, and it is stated that in 20 per cent. of the cases the result has been fatal. The sanitary authority seem to recognise the special influence of the elementary schools in this diffusion, for they have not only closed them, but they have, in addition to processes of disinfection, ordered the destruction of books, maps, and other school property by which the infection may be retained.

THE PURITY OF CHLOROFORM.

IN a daily contemporary a curious mixture of "fact and fiction" recently appeared anent the dangers of impure chloroform. While we heartily concur in the general tenour of the writer's remarks, we feel bound to set him right in his facts. He refers to the researches of the younger Dr. Du Bois Reymond upon Pictet's chloroform, but omits to mention the eminent chemist's name or to credit him with his undoubtedly meritorious efforts to free chloroform from some of its dangers. The writer then quotes Dr. Du Bois Reymond, jun., and avers that "this high authority" says chloroform is often administered in a room "not designed for the purpose," and inferentially implies that thereby risk is run. This seems to us refining a little too far. If a room is large enough for a dwelling-place and is not lighted by illuminating gas, we fail to see why chloroform cannot reasonably be given in it, and no houses, save possibly those of the very poor, are without one such room; while in the case of the indigent, as a rule, the doctor sends the case to the hospital. Ventilation and absence of lighted gas are really the only desiderata. Again, exception is taken to the quality of the chloroform in general use, which is stated to be less pure than that described in the Pharmacopœia. Such a gratuitous statement cannot, of course, be answered, as no evidence one way or the other exists; but what the writer in question does not seem to be aware of is that the impurities upon which Dr. Du Bois Reymond lays such stress were those found even in the best samples of the drug, whether B.P. or not, but existing in so minute a quantity that a very large amount of the drug had to be crystallised before an appreciable amount of the refuse chloroform was obtainable. Nor could such impurities be discovered by ordinary tests. This being so, the statement—not strictly accurate, by the way, as the standard books give the rules for testing chloroform—that nowhere is "the physician" (*sic*) enjoined to test his chloroform before mixing it, is of less importance than at first seems apparent. As a rule, chloroform is not administered "pure," because, unless some spirit be added to it, it very rapidly undergoes decomposition, and is unfit for use; but the addition of alcohol obviates this, and if it be kept cool and out of contact with light it remains constant. Persons who undertake to give chloroform should of course respire the vapour themselves, test its reaction and smell, and this is always done; but to fractionate or freeze and distil the mother liquor is a task which, were the average medical

Digitized by Google

man required to undertake it, would severely test not only his chloroform, but his time and pocket, and would need the command of the special apparatus at present the sole property of M. Pictet. Referring to the inferiority of the chloroform commonly used when compared with that of the B.P., the writer makes the following remarkable statement:—"It is for similar reasons that ether, otherwise unduly extolled by English authorities, is considered entirely unfit for use in India." A more mixed statement could hardly be imagined. Of course, ether cannot be used in India, owing to the extreme difficulty of obtaining and keeping so highly volatile a body in any but a temperate clime. Nor, on the other hand, must the chloroform of India be regarded as being exceptionally pure, as the well-known firm which supplies both Scotland and India also very largely supplies England. Whether chemical purity be an absolute necessity for chloroform has yet to be decided, nor can it be said at present how far Dr. Du Bois Reymond's work upon the lower animals is to be taken as absolutely on all fours with the experience of surgeons with their human patients. The statement that in nine-tenths of the reports of cases no mention is made of the purity of the drug is an exaggeration. We shall very shortly show that a considerable amount of information under this head has been given in the reports.

THE ALKALOIDS OF ACONITUM NAPELLUS.

TWO papers of unusual interest were read at the last meeting of the Chemical Society on the 3rd inst. by Professor Dunstan. The first paper was a record of the research carried out jointly by Mr. Umney and Professor Dunstan on the properties of the roots of aconitum napellus. For the purpose of experiment they dried the fresh roots at a low heat, and then, after powdering, exhausted them with fusel oil. The alkaloids were dissolved out of the fusel oil with weak sulphuric acid, and the acid mixture was treated with chloroform to remove resin. The liquid was next made alkaline with ammonia and shaken with ether and then with chloroform. The ethereal solution yielded a gummy residue, from which they extracted aconitine as a crystalline hydrobromide, all attempts to crystallise the residue having failed. Crystalline aconitine was successfully prepared from the hydro-bromide, and it was found that the base dissolves only to the extent of 1 in 4431 of water. The base does not appear to exist naturally in a combined state, as the juice squeezed out of the fresh root contained very little aconitine. All attempts to crystallise another alkaloid found in the ethereal liquid failed. It possesses a bitter taste, does not produce numbness, and Mr. Umney and Professor Dunstan have given it the name "napellin." The chloroform solution contained aconine, $C_{26}H_{41}NO_{11}$, the properties of which and its relation to aconitine formed the subject of the second paper, contributed by Professor Dunstan and Dr. F. W. Passmore. The authors showed that by heating aconitine with water in a sealed tube at 150° C., aconine and benzoic acid are formed, as originally stated by Wright and Luff. The properties of aconine have been studied; it is dextro-rotatory, while its salts, like aconitine, are laevo-rotatory. The authors made attempts to synthesise aconitine by heating aconine with ethyl benzoate, and the successful results which followed the experiments are calculated to be of the utmost importance to pharmacy and medicine. The action which takes place may be represented as follows: $C_{26}H_{41}NO_{11}$ (aconine) + $C_6H_5CO.OC_2H_5$ (ethyl benzoate) = $C_{26}H_{40}(C_6H_5CO)NO_{11}$ (anhydro-aconitine) + C_2H_5OH (ethyl alcohol). Anhydro-aconitine so obtained forms aconitine with water. The experiment indicates that aconitine is mono-benzoyl aconine. $C_{26}H_{40}(C_6H_5CO)NO_{11}$. One or two derivatives were prepared—aconitine methyl iodide, for example—the physiological action of which, as well as the other new compounds, are being studied.

END OF THE STUDENTS' STRIKE IN ITALY.

THE academic cyclone on which we commented on the 27th ult. has "stormed itself out." At Rome on Saturday last, in the Giocchino Belli Theatre, a mass meeting of students was held, at which an order of the day was proposed to the following effect: that while the *cives* of the University resumed their studies they demanded a free pardon for the three of their number who were undergoing punishment at the hands of the Senatus. To this a counter-order of the day was moved: that "the students simply resumed their studies." At this the few ringleaders of the strike broke out in a storm of hisses and hootings. The mover of this order of the day being denied further hearing, his supporters left the hall *en masse* under protest. Those who remained ultimately approved the following: "The students of the University of Rome, yielding to violence, resolved to return to their classes." The "violence," be it noted, was the determination of the Senatus to maintain discipline in the case of the three offenders. So ends the great academic strike, for, after the Roman students have "climbed down," those of the provincial seats of learning will no longer defy their professors. A sharp lesson has thus been taught the academic youth of Italy, and we hope it will be a lasting one. Politics in the undergraduate stage were forced on the students of a past generation when their country's unity and independence were at stake. Now that that consummation has been effected, there is no excuse for political preoccupation—certainly none for a premature indulgence of the demagogic spirit—in the undergraduates of the present day. It rests with them to remove, or at least not to justify, the reproach fastened on Italy by one of her most patriotic sons—the reproach of being "a carnival nation," fonder of the cheap triumphs of the piazza than of steady, prosaic work.

THE DIAGNOSIS AND PROGNOSIS OF SYPHILITIC DISEASE OF THE BRAIN.

DR. OTTO HARMSEN has been induced by the scarcity of information relating to syphilitic disease of the brain to publish particulars of nine such cases, which had remained under observation for a year or more in the Berlin clinic for nervous diseases. The *Archiv f. Dermat. u. Syph.*, which publishes the account, points out that the meagre statistics of this affection have often been complained of, more especially by Naunyn. The chief symptoms in most instances were headache, vomiting, vertigo, facial paralysis, aphasia, and hemiplegia. In one case polydipsia and polyuria appeared some years after the primary infection, and serious cerebral symptoms quickly followed. In another case the nervous symptoms appeared as early as two years after the initial sore. Nearly all the cases were cured by energetic anti-syphilitic treatment, this being most marked in a patient never before treated with mercury. It should be mentioned that in many instances a temporary disturbance of the reaction of the pupil was the first and only indication of cerebral mischief, as has been pointed out by Oppenheim.

THE TREATMENT OF REDUCIBLE HERNIÆ BY THE INJECTION OF ALCOHOL.

EDWARD STEFFEN of Zurich, during the past three years, has treated 326 cases of reducible herniæ by Schwalbe's method, and has published the results in the *Correspondenz-blatt für Schweizer Aerzte*. In most instances the patients were able to continue their work during treatment. After the injection the puncture was cleaned and covered with mercurial collodion. Notwithstanding, in a few cases,

Digitized by Google

sloughing took place; but this acted rather beneficially than otherwise. The number of injections in a single case varied from 6 to 168, the latter extending over a period of two years and a half. A medium-sized rupture in an adult required from 80 to 100 grammes of alcohol. The author used alcohol 70 per cent. in doses of one to four grammes, substituting in exceptional cases extract of oak bark. Latterly he found the addition of phosphoric acid, in the proportion of 1 to 200, advantageous. In thirteen cases the result of the treatment is not known, in twenty-nine a cure was not possible from various causes, such as obesity or size of the rupture; of the remainder, 245 cases are reported cured and 19 improved. The longest time taken to effect a cure was four years, the shortest one year. Of 257 inguinal herniæ, 216 cases were cured and 16 improved, with 23 relapses. Of 13 femoral herniæ, 9 were cured and 2 improved, with 1 relapse. Of 19 umbilical herniæ, 17 were cured, with no relapse. Of 4 herniæ in the linea alba, 3 were cured, the other improved. It appears that the more recent the hernia and the younger the patient the more favourable the prognosis, and the ambulant treatment, with intervals of three to seven days between the injections, gave better and more lasting results than the treatment in bed with daily injections.

FOREIGN UNIVERSITY INTELLIGENCE.

Buda-Pesth.—Dr. J. Arkövy has been promoted to an Extraordinary Professorship of Odontology.

Prague (German University).—Dr. A. von Rosthorn of Vienna has been appointed to the chair of Gynæcology.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. George Athanasovitch, a member of the first Bulgarian Ministry under Prince Alexander.—Professor Credé, the distinguished gynæcologist, of Leipsic.

THE annual dinner of the Medical Society of London was held in the Whitehall Rooms at the Hôtel Métropole on the evening of March 12th. Dr. Douglas Powell occupied the chair, and was supported by the President elect, Mr. Hutchinson, and the President of the Royal College of Surgeons. The list of speeches was short, but they did not lack in excellence. Among the speakers were the President, Mr. Hutchinson, Sir J. Crichton Browne, Mr. Brudenell Carter, and Dr. Allchin. A special and most pleasant feature of the evening was the excellent singing of Dr. Frederick Roberts and Mr. Anderson Critchett, which was very fully appreciated. Upwards of 160 Fellows and guests dined, the number being larger than on any previous occasion. A very enjoyable evening was spent, and the prosperous condition of this ancient Society was fully demonstrated.

Pharmacology and Therapeutics.

TELLURATE OF POTASSIUM IN NIGHT SWEATS.

THE effect of tellurate of potassium in arresting the night sweats of phthisis having been shown by some observations by Dr. Neusser, his results have recently been confirmed by a Polish physician, Dr. Poborecky, who employed the remedy in fifty cases. It was prescribed in the form of pills, and was commenced in doses of one-seventh of a grain, gradually increasing to a grain. Usually less than half a grain in the evening was sufficient to prevent sweating during the night. It was found, however, that day sweats required rather larger doses than night sweats for their prevention. The action of the drug was generally manifested in about three-quarters of an hour, but in the more obstinate cases the effect passed off, and the sweating began again in from five to seven hours. In cases of less severity the effect was more lasting. No untoward action on the stomach was produced by a dose of two-thirds of a grain, and only by long-continued doses of a grain, and in exceptional cases, were eructations and loss of appetite produced. These symptoms, however, ceased on stopping the medicine. The only unpleasantness due to the tellurate was the garlic-like smell imparted to the breath, and this, though evident to other people, even for some time after the drug had been stopped, was not so perceptible to the patient. In order further to test the anti-sudorific qualities of tellurate of potassium, it was given to healthy persons in hot weather, and was found to be capable of entirely preventing perspiration in doses of a third or even of a sixth of a grain.

DIAPHORETIC PROPERTIES OF WILD ROSEMARY.

Dr. Schnabl, writing in a Polish medical journal, mentions as a valuable sudorific the wild rosemary, Ledum palustre, or Rosmarinum sylvestre, which is used in some parts of the country as a household remedy. The herb must be gathered when flowering. It is then dried and kept in sealed boxes. The leaves contain, according to Meissner, a volatile oil, from which, after long standing, a kind of camphor separates out; the other constituents found in the leaves are tannin, a gum resin, citric acid with traces of acetic, formic, and valerianic acids, a bitter extractive matter, and ericoline. An infusion of from a drachm and a half to three drachms is sufficient to produce perspiration. A century ago this drug was prescribed by physicians as an expectorant. It is also considered as an astringent by some, and has at various times enjoyed a reputation in many different maladies.

BINIODIDE OF THIOPHENE.

This drug, which is an analogue of iodol, contains 75·5 per cent. of iodine and 9·5 per cent. of soda. It is insoluble in water, but readily soluble in warm alcohol, ether, and chloroform. Dr. A. Hock of Vienna considers it a good substitute for iodoform in dressing wounds. It checks the formation of pus and prevents exuberant granulation. It can be used either as a powder or in the form of gauze, the latter of which is prepared by soaking the material in the following solution: Biniodide of thiophene, 5 parts; rectified spirit, 50 parts; sulphuric ether, 50 parts; glycerine, 1 part.

THE EMPLOYMENT OF DIURETIN IN CHILDREN.

According to Dr. R. Demme of Berne this drug can be given to children between two and five years of age in doses of 0·50 gramme daily, and in doses of 1·50 grammes to those between six and ten. In infants under one year it is liable to cause gastro-intestinal irritation. It appears to act upon the renal epithelium, and has proved of service in the dropsy of scarlatinal nephritis as well as in that due to mitral disease, after digitalis had proved ineffectual. Its action is not cumulative, but in one case of amyloid degeneration of the liver, kidneys, and spleen its use caused an erythematous rash, accompanied with profuse diarrhœa.

BROMAMIDE.

Dr. Augustus Caillé, in the *New York Medical Journal*, gives a preliminary report of an experimental research into the therapeutic value of bromamide, a new antipyretic and anti-neuralgic remedy. The drug, which was discovered by Messrs. Fischedick and Koechling of New York, is a new bromine compound of the anilide group containing 75 per cent. of bromine ($C_6H_2Br_3NHHBr$). Experiments as to the therapeutic properties of bromamide were conducted at the German Hospital for six months in various affections, including typhoid fever, acute rheumatism, chronic nephritis, various forms of neuralgia, &c. It appears that bromamide has the power of reducing the temperature in most cases of febrile disease from 1° to 2·5° F., without the excessive sweating produced by other antipyretic drugs. The dose is ten to fifteen grains as an antipyretic and antineuralgic, and may be administered in capsule, wafer, dry upon the tongue, or suspended in a fluid.

SOLVEOL AND SOLUTOL.

Solveol is a liquid prepared by dissolving cresylol in a solution of cresotate of soda. It is miscible with water in

Digitized by Google

all proportions, giving clear neutral solutions. It is an analogue of lysol, but it does not render the hands greasy like the latter and creoline. It is almost without smell, and possesses antiseptic properties superior to those of carbolic acid. In surgery a ½ per cent. solution is used. Solutol differs from the above in the fact that a solution of cresylate of soda is used to dissolve cresylol. This antiseptic cannot, however, be used in surgery on account of its caustic properties.

EFFECTS OF SALICYLATE OF SODA IN EXCESSIVE DOSES.

Dr. Frederick W. Mann, in a recent number of the *New York Medical Record*, records an instance of the serious and alarming effects produced by this drug in large quantity. He had prescribed for a patient suffering from acute rheumatism salicylate of soda in four-grain doses every two hours. The patient, however, finished the contents of his bottle—amounting, in all, to two drachms of the drug—within the space of four hours. He soon began to suffer from hallucinations, and finally became quite maniacal. After spending a night in a police cell he was removed to a hospital, and during the next few days he suffered from a condition closely resembling delirium tremens. When spoken to he responded pleasantly, and showed no coarseness of speech or action; his violence arose simply from his attempts to elude his imaginary pursuers. At the end of five days the hallucinations disappeared, and recovery was complete.

TREATMENT OF DYSENTERY.

Drs. Lardier and Pernet strongly recommend the use of salol and iodoform in the treatment of dysentery. Salol, in four-grain doses suspended in mucilage, acted in a most salutary manner; but iodoform—from four to six grains daily, combined with opium—gave the most beneficial results. The iodoform was given in capsules, each containing three-quarters of a grain of iodoform and a quarter of a grain of opium, to be taken five or six times during the day. The pain and tenesmus were relieved by warm boracic acid enemata, and in obstinate cases by a suppository containing hydrochlorate of cocaine and opium. In addition to this treatment great cleanliness was observed, the patient being washed daily with a saturated solution of boracic acid or with a solution of corrosive sublimate of the strength of 1 in 500.

REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

THE Medical Officer's report for 1890 appears as the supplement to the twentieth Annual Report of the Local Government Board, and it deals exclusively with the work carried out in the medical department. The vaccination returns form a forecast of an increasing laxity in the administration of the Vaccination Acts, which we fear is largely due to the determination of a number of authorities to discontinue the performance of their statutory duty during the sittings of the Royal Vaccination Commission, and which may at any moment bring about serious results. In 1881 the births unaccounted for as regards vaccination were 5·7 per cent. of the births in the metropolis and 4·3 in England; whereas the figures stood 10·3 and 8·2 respectively in 1888; and the increase of default will doubtless be found to be still greater since then. A considerable number of medical reports are reprinted in the volume, together with introductory comments by Dr. Buchanan. Some of these reports we reviewed at the time of their issue, notably that by Dr. Barry, on the Tees epidemic; that by Dr. Blaxall, on Staines rural district in relation to the state of the Thames above the intakes of the London water companies; that by Dr. Parsons, on epidemic pneumonia at Scotter; that by Dr. Low, on suspected cerebro-spinal meningitis in Lincolnshire and adjacent counties; and also that by Dr. Parsons, on the epidemic of influenza. All but the latter, which has been published as a separate volume, are reproduced *in extenso*, and they thus form part in the permanent record of the work of the department.

Then comes a lengthened report on an inquiry into certain systems which have been adopted in northern and midland districts, with a view of utilising slop-water for the purposes of water-closets, or of providing trough-closets, the desire on the part of certain authorities being to secure the water-carriage of excreta without the complication and expense of water-closets as commonly constructed. Both forms of closet reported on appear to answer certain limited purposes, provided they are of proper construction, and Dr. Parsons gives a lengthy description of their cost, adaptability to certain localities and classes, and of the conditions which are essential to their success, his report being freely illustrated by diagrams. All such closets must be out of doors; and as regards the slop-water closets, it is clear, as we have more than once pointed out, that success can only be obtained where the slop-water, after being allowed to accumulate, is then automatically discharged in bulk along the drain, so as to clear out the pipe or other receptacle into which the excreta are first received. If this and certain other conditions are not complied with, it seems pretty clear that greater nuisance will arise from slop-closets than is associated with several improved forms of ash-closet and other so-called dry-closets.

One very interesting chapter in the volume is that in which Dr. Ballard, who has recently retired from official life, gives a summary of his own labours and those of others in tracing out the causes of occurrences of disease of a specific character which have resulted from the use of infected articles of flesh food. These diseases have come to be styled cases of food-poisoning, and Dr. Ballard's name has been very closely identified with their study, both clinically and etiologically. He speaks, therefore, with authority when he gives his view as to the circumstances under which they are brought about. Discussing this view, Dr. Buchanan says:—"Dr. Ballard is disposed to infer that, in this class of cases, the morbific quality has commonly not been inherent in the animal furnishing the food, but has been obtained by the food *from its surroundings* during the time that the food-material was being kept"; and he adds a warning as to the bearing of this view on maintaining wholesomeness in all larders, pantries, and other places where human food is kept for sale or otherwise stored. Some account is also given of the preliminary work which has been done by Mr. Power, Dr. Barry, and Mr. Thompson in relation to the serious prevalence of lead-poisoning which has followed, at curiously irregular intervals, on the use of certain moorland waters for drinking purposes. Information on the subject has already been obtained from several hundred medical officers of health; and the extent of the mischief may be judged of when it is explained that even a preliminary record goes to show that the health of no less than 600,000 persons is involved in the subject. Hitherto efforts seem mainly to have been directed to methods of remedying the mischief after it has been allowed to take place; the present investigation has, however, been undertaken with a view of getting at the root of the mischief, for it is announced that its prime object is to learn how the waters in question come to acquire a power of dissolving lead. This is obviously the proper function of a health department, prevention, rather than cure, claiming its first attention.

Turning next to Dr. Buchanan's record of the auxiliary scientific investigations, we find that the study of the pathology of diphtheria has been continued by Dr. Klein, who reports additional instances in which inoculation of milch cows with cultures of the bacillus diphtheriæ have given rise to disease having the same pathological characters as those previously witnessed. In one such case the milk itself contained the characteristic bacillus at one stage, but not at another stage. Further work has been done by way of studying the influence of concurrent infections in the same animal; and in one instance, where the chemical products obtained by the growth of bacillus pyocyaneus were used to see whether they exerted any antagonism on the subsequent inoculation of the bacillus of diphtheria, it was found that, instead of any antagonistic action, the chemical products in question served rather to enhance the activity of the resulting disease. But as regards experiments bearing upon tuberculosis now in progress, Dr. Klein reports that "evidence has already been attained to justify

Digitized by Google

an expectation that the chemical products of bacillus pyocyaneus will be found to have distinct inhibitory action on the tuberculous process."

Dr. Sydney Martin's investigations, following on his former ones in 1889, into the chemistry of anthrax go to show that whereas the anthrax albumoses, and not the alkaloid, give rise to the fever of anthrax, it is to the anthrax alkaloid that the local œdema and coma of anthrax are due. "The albumoses," writes Dr. Buchanan, "as such, have indeed seemed to possess but little specific quality, the fever produced by them being much the same as that producible by the familiar albumoses of peptic digestion. It is essentially, it would appear, the alkaloid (resulting from further change of the albumoses) which is the cause of the specific phenomena and of death in anthrax." The bearing of this on other specific infections is obvious, and Dr. Martin's other investigations as to the meaning of bacilli having on the one hand virulent, and on the other attenuated, characteristics are equally interesting. Amongst other contributions is one by Dr. Hamer, who, in studying the question of susceptibility and insusceptibility, has investigated the doctrine of phagocytosis, a doctrine which, it is admitted, cannot at once solve the difficulty with which the investigator finds he has to deal. Dr. Andrewes has also made examination of the micro-organisms associated with suppuration and with phlegmonous and other inflammation in man. Dr. Buchanan reports that in this work Dr. Andrewes has, amongst other things, made study of the life history of staphylococcus pyogenes within the bodies of the experimental animals, but that some of his ends were frustrated by his inability to obtain the erysipelas organism in an active state, facilitating comparison between the *streptococcus* of that disease and the streptococcus pyogenes. Whether the more exclusively scientific or the public health aspects of the volume be considered, it will be found one well worthy of study.

THE REPORT OF LORD WANTAGE'S COMMITTEE.

No. II.

WE concluded our previous article by saying that the present Government, with a general election in front of it, was not at all likely to grapple with a big and expensive military question. Still, it is certain that it must be undertaken sooner or later; and we shall be surprised if some more radical changes are not then proposed than any which have as yet been suggested. Meanwhile the divergence of opinion between Sir A. Haliburton and his colleagues is too wide, and some of the more prominent features in the report of Lord Wantage's Committee have been too seriously damaged by his vigorous criticism, for any War Minister to adopt the Committee's recommendations as part of a Ministerial policy. Nevertheless, as we have said, the report of the majority of the members is in many respects an able and interesting document, and, constrained as they were to run on existing lines, some of their proposals seem both pertinent and practical. As the Committee point out, the regulation prohibiting all recruiting beyond the army establishment annually voted by Parliament prevents advantage being taken of a favourable state of the labour market to provide for clearly foreseen needs. Checks are placed on recruiting when recruits can be had. The Committee suggest that, at any rate, it should be permissible to recruit above the establishment, so long as the average numbers maintained during the financial year do not exceed the numbers voted by Parliament. This seems a sensible suggestion. The Committee proposed modifications in the term of service, so as to make it as easy and elastic for the private soldier as possible. An army that depends upon voluntary enlistment must move with the times and adjust itself to popular requirements. As far as practicable, and without risk of grave prospective injury to the maintenance of an adequate reserve, the man who desires to continue with the colours and make the army his profession should be allowed to do so; and, on the other hand, if a man has strong reasons for leaving the colours and going into the reserve, he should not be prohibited from doing so. The function of a reserve is to complete the battalions for war service, and not to be a substitute for them, as would practically be the case now.

Foreign service, and especially service in India, is a great drain on the youth and manhood of the army, and the provision of drafts of a certain age and service for India depletes the home battalions, and is a recurring source of difficulty. As Lord Wolmer pointed out, battalions of very young and immature soldiers have a very high hospital admission-rate. In the case of the 2nd Battalion of the Suffolk Regiment, for example, which went to Egypt, it was 1406 per 1000. As the reserve, according to Mr. Stanhope, will soon amount to a strength of 80,000, it does not seem to us impracticable to introduce more elasticity into our system in the directions indicated. As regards such corps as the Royal Artillery, and the garrison artillery especially, every inducement should be held out to retain the services of technically trained men.

According to the present system, the militia is supposed to act as a nursery for the regular army. Might it not be preferable to reverse the position and make the latter feed the militia as part and parcel of the reserve, by which the military training of the men would be maintained to some extent, whereas the reserves at present get no training. The increase of pay recommended by Lord Wantage's Committee practically amounts to a proposal to offer the soldier seven shillings a week clear, with good board, lodging, and clothes. It cannot be said, as a matter of common sense and fairness, that these are extravagant terms to offer in exchange for efficient labour of the kind which soldiers are called upon to perform. But it is urged that this would in the aggregate amount to a large sum, and would not, after all, have the desired effect of inducing a proportionately larger number of men of nineteen and twenty years of age to enlist. We are inclined to think there is much force in this objection. But it would, we believe, attract a larger number of more desirable young men than the present terms, and there would, in any case, be a proportionately greater choice, the stronger and older lads could be selected, and the physical standard would consequently be raised. As regards deferred pay, the committee would abolish the present system in favour of one of gratuities of smaller amount, and the sum saved in this direction would go towards lessening the expense of their proposals for the soldier's benefit in another. A large majority of the men—and it is a soldier's question—are in favour, however, of maintaining the present system, which has not yet been in operation long enough to warrant a final decision as to its working.

Sir A. Haliburton's report, with its tables, figures, financial estimates, and bases of comparison with continental armies, has a kind of precision and method which give him a firmer foothold than his colleagues. Sir A. Haliburton estimates the cost of the Committee's proposals at a million and a half. Assuming this to be the case, the question at once arises whether this new expenditure could not be met by economies effected in other directions.

Adverting to narrow-minded prejudices against the army exhibited by the refusal to admit soldiers in uniform to places of entertainment and the like, the Committee suggest that the War Office, as the guardian of the rights and position of soldiers of the British army, should take steps to test the legality of such refusals. This kind of prejudice is keenly felt by soldiers, and is said to exercise an adverse influence on recruiting. This gives us an opportunity of inquiring, *en passant*, whether the class of accommodation provided in London, for example, for the examination of recruits, does not also exercise a prejudicial influence. Instead of having good, airy, and attractive quarters in a good position, the recruiting establishment at St. George's barracks is approached through a dirty back street, and is a very uninviting sort of place, but little calculated to make a favourable impression on a respectable recruit. It is open to question whether the authorities go the best way to work in this respect, and in advertising for recruits. The recommendation that the soldier should have two kinds of uniform — one for work, the other for show—is a sensible one. And, from a hygienic point of view, we consider that the number of sentries should be diminished. There is probably nothing that tells more on the health of young men, or is more unpopular, than the large and apparently unnecessary amount of night work in the army. A certain amount there must be of course, even as a matter of military training, but, to take the case of the Guards for example, the night duties are an important factor in causing inefficiency and waste

Digitized by Google

from sickness and invaliding. It is very important, too, to avoid over-pressure in trying to form raw recruits into complete soldiers in the shortest possible time. Their habits of life are suddenly changed, they have often been underfed before enlistment, and are easily fatigued, and with one thing and another they find they have no time to themselves. It is not surprising that, under such circumstances, the recruit acquires a distaste for the service. We feel bound to say, however, that much more care is exercised nowadays in this respect. We think the Committee is right in urging the claims which our discharged soldiers and sailors have upon the State for employment in any posts for which they are qualified, as recommended in the report of Mr. Childers' Committee, and believe that it would give an impetus to recruiting. The day has gone by for exclusive privileges, and the Guards, as we have said already, should take their turn of foreign service, as far as the Mediterranean stations are concerned at any rate; and if there were a battalion of Footguards composed of soldiers selected from our infantry for physique and war service it would be a popular measure. Moreover, the stimulus of reward of some kind is necessary for soldiers as for other people. If it cannot be given in the way of increased pay it might be in another direction—viz., a greater number of commissions might be open to the rank and file than at present.

To conclude, it seems to be generally agreed that there must be as many battalions at home as there are abroad if the existing system is to work properly at the present time. And as regards the near future, the soldier's pay and advantages will have to be increased if a voluntary army of adequate strength has to be maintained. The appointment of committees and the adoption of different expedients will only postpone a decision of this question for a season.

ROYAL MEDICAL BENEVOLENT COLLEGE.

DR. C. HOLMAN, treasurer of the College, asks us to publish the following appeal:—

The Council are of opinion that on no previous occasion since the establishment of the College has so important a proposition been brought before their subscribers and before the profession at large. They earnestly hope that many medical men will exert themselves amongst their friends and patients, and make the ensuing festival a successful beginning of an alteration the benefits of which, to both pensioners and scholars, are simply at present not to be calculated.

Dear Sir,—On Tuesday, April 5th, the Right Hon. the Lord Mayor of London has consented to take the chair at the biennial festival of the College.

At this dinner the Council desire to raise funds: 1. To assist in meeting the annual outlay for the support of the fifty pensioners and fifty foundation scholars, an outlay amounting to between £5000 and £6000. 2. To aid in raising a sum of about £26,000, so that the Council may give the pensioners augmented incomes, and thus dispense with their compulsory residence at Epsom College, and enable them to spend their declining years amongst their relatives and friends.

That this is a truer form of charity has been of late years fully recognised; the system of pensions as opposed to compulsory residence in almshouses has been adopted by H.M.'s Government in the case of the Greenwich Hospital, and by many of the best known charities in England.

The suggestion, however, has in addition to its charitable side one which the Council submit is of almost as great importance.

It has been forced on the Council that the school cannot be carried on as it should be unless its accommodation is in all ways increased. Thanks to the unremitting and successful efforts of the head master and his staff, the school is full, and from the inquiries made respecting it, and from the number of names down on the list waiting for admission, there appears no reason to doubt that this satisfactory state of things will continue.

Even, however, with the present numbers more room is wanted for convenience, and therefore efficiency, in teaching and for general school purposes, so that if the numbers are to be *increased* an immediate and large *extension* of accommodation must be provided. This weighs very heavily on the Council who have the management of the school, and hence their urgent appeal to the public.

Any enlargement of the existing school buildings must, even when carried to its utmost limit, be a mere palliative, so that new buildings are essential; and if the pensioners could be provided for elsewhere the buildings they now occupy could be at once utilised, and so provide for an important part of the necessary extension. Thus a double benefit to the pensioners and to the school would accrue, and in this benefit the boys on the foundation, who are an integral part of the school, and who differ from the rest only in that they are educated and maintained free of cost to their relatives, take their full share.

The Editors of THE LANCET, impressed with the value of this scheme, have most liberally offered £1000 if the full amount be collected.

Some of the public recognise the very important services which the medical profession render to the community, and to them it is hardly necessary to appeal, or to do more than to state that money is wanted urgently for the objects set out above, to secure their cooperation.

Many, however, do not recognise the peculiar position in which a medical man stands. He is bound (if he does his duty, and there are few who do not) to hold himself at all times and in all weathers at the disposal of those who may want his help. He attends the poor as well as the rich, he goes to places and houses insanitary as well as sanitary, he exposes his life in all climates and at all seasons, with the result that the lives of medical men are shorter than those of men following other professions, and the time within which they can provide for their families is proportionately shorter. "The medical death-rate is far in excess of the rates in the other learned professions, and also of the rates in most trades and industries. .... The general result of the comparison is to show that, with very few exceptions, the mortality of medical men is higher under every heading than the mortality of males generally, and that under some of the headings the medical mortality is twice or thrice, or even more times, greater than the average."[1]

All these facts show how difficult it must be for medical practitioners to make adequate provision for their families, and accounts in some measure for the very large amount of distress which necessarily exists amongst the widows and orphans of medical men.

The Council earnestly hope that you will aid them in the great work they have in hand: firstly, in meeting the necessary annual outlay to fulfil the trust bequeathed to them by the founder; secondly, to secure at as early a date as possible an improved position for the pensioners; and, thirdly, to assist them in maintaining the school in its present state of efficiency, and in raising it to the level of the first schools of the country, a position to which it is fast attaining.

We shall gladly take charge of any donation or subscription you will kindly entrust to us. Ten guineas, or one guinea annually, constitute a governor.—We are yours very faithfully,

J. FAYRER, M.D., F.R.S., K.C.S.I., Chairman of Council.
C. HOLMAN, M.D., Treasurer.
J. L. PROPERT, M.B., Chairman of Festival Committee.
J. B. LAMB, Secretary.

37, Soho-square, W.

THE ROYAL BRITISH NURSES' ASSOCIATION.

THE Draft Charter submitted by this Association, with its petition for incorporation, to the Privy Council recites in the name of Her Majesty—

"That it has been represented to us by our most dearly beloved daughter Helena, Princess Christian of Schleswig-Holstein, Princess of Great Britain and Ireland, that in 1887 a Society was established in London called the 'British Nurses' Association,' which has since its establishment been joined by more than 3000 nurses, each one of whom has been engaged for three years or more in attendance upon the sick; that the said Association was not established for the purpose of gain, but for the purposes of the improvement of the profession of nurses and of the promotion of their efficiency and usefulness and of assisting them by various benevolent schemes; that in furtherance of the said objects a list of nurses has been compiled and published setting forth the names and addresses of nurses, with the names of the hospitals or institutions at which they have been trained and the length of training which each has received, thus enabling the public to form a more accurate judgment of the professional education and experience of the nurses so registered; that a benevolent fund has been established for the purpose of giving aid to nurses, and that the management of the said Association is vested in certain eminent members of the medical profession, matrons of hospitals, and other persons interested in nursing; and that in 1891 we were graciously pleased to confer on the said Association the prefix and title of 'Royal' and to command that the said Association should be styled the 'Royal British Nurses' Association.'"

It then proceeds, after some additional and merely formal recitals, to declare—"That our said most dearly beloved daughter Helena, Princess Christian of Schleswig-Holstein, Princess of Great Britain and Ireland, our trusty and well-beloved Sir James Paget, Baronet; Sir Spencer Wells, Baronet; Sir William Savory, Baronet; Sir Richard Quain, Baronet; Sir Joseph Fayrer, Knight Commander of the Most Exalted Order of the Star of India; Sir Henry Thompson, Knight Bachelor; Sir James Crichton Browne, Knight Bachelor; Sir Dyce Duckworth, Knight Bachelor; Sir Edward Sieveking, Knight Bachelor; Sir Alfred Garrod, Knight Bachelor; Sir George Humphry, Knight Bachelor; Robert Brudenell Carter, Fellow of the Royal College of Surgeons of England; John Williams, Doctor of Medicine; William Bezly Thorne, Doctor of Medicine; Bedford

[1] William Ogle, M.D.Oxon., F.R.C.P., Registrar-General.

Digitized by Google

Fenwick, Doctor of Medicine; Isla Stewart (Matron and Superintendent of Nursing of St. Bartholomew's Hospital); G. M. Thorold (Lady Superintendent of the Middlesex Hospital); Ethel Gordon Fenwick (Lady Matron and Superintendent of Nursing of St. Bartholomew's Hospital); Cassandra Beachcroft (Lady Superintendent of the Lincoln County Hospital); Margaret Breay (Acting Matron of the Metropolitan Hospital); Mary N. Cureton (Lady Superintendent of Addenbrooke's Hospital, Cambridge); Christina Forrest (Lady Superintendent of the York County Hospital); Louisa Hogg (Head Sister, Royal Naval Hospital, Haslar); R. F. Lumsden (Hon. Lady Superintendent of the Royal Infirmary, Aberdeen); Henrietta C. Poole (Nursing Superintendent, Adelaide Hospital, Dublin); Gertrude A. Rogers (Lady Superintendent of the Leicester Infirmary); Georgina Scott (Lady Superintendent of the Sussex County Hospital); Maud G. Smith (Lady Superintendent of the Royal Infirmary, Bristol); Catherine J. Wood (late Lady Superintendent of the Children's Hospital, Great Ormond-street); and all other persons who, pursuant to this our Charter, become members of the Corporation established by this our Charter, shall be a body corporate by the name of the Royal British Nurses' Association, having a perpetual succession and a Common Seal," together with the usual incidents of incorporation which are duly set out.

It next proceeds to set out the purposes and powers of the Corporation as follows: "1. The maintenance of a list or register of nurses, showing as to each nurse registered her name and address, and the name of the hospitals or other places at which she has been trained and the length of training which she has received. 2. The founding and maintenance of schemes for the benefit of nurses in the practice of their profession and in times of adversity, sickness, and old age. 3. The promotion of conferences, public meetings, and lectures in connexion with the general work of the Corporation. 4. The doing anything incidental or conducive to carrying into effect the foregoing purposes."

Then follow certain ancillary clauses in common form, and a staff of officers is provided, to the following effect: "There shall be a President of the Association, and such number of honorary officers as the Association may from time to time think fit to appoint. The first President shall be Her Royal Highness Princess Christian of Schleswig-Holstein. The first honorary officers shall be those persons who at the date of this our Charter are honorary officers of the Royal British Nurses' Association in the recitals of this our Charter specified. On the resignation or death of the President or of any honorary officer, and as occasion may arise, the vacancies shall be filled up by the General Council hereinafter mentioned upon the nomination of the Executive Committee hereinafter mentioned. The President shall preside at all meetings of the Corporation and at all meetings of the General Council and Executive Committee, or of any sub-committees thereof at which she may be present. The President shall have power to summon meetings of the Corporation at any time she may think fit so to do, in order to submit to the members thereof such matters of importance relating to the affairs of the Corporation as she may deem requisite."

The members of the Corporation are defined to be—"1. The President. 2. All persons who at the date of this our Charter are members of the Royal British Nurses' Association in the recitals of this our Charter specified. 3. Persons from time to time elected as hereinafter mentioned, and being either (*a*) medical practitioners duly qualified to practise as such in any part of the British Empire according to the laws for the time being in force; (*b*) nurses (subject to such conditions as may be prescribed by the by-laws for the time being in force). 4. The Corporation may provide by by-laws for the admission of other persons to honorary membership."

In view of recent discussion as to the by-laws of the College of Surgeons, some special interest will naturally be felt in the provisions concerning general meetings. "There shall be a general meeting of the members of the Corporation within the space of six calendar months after the date of these presents. An annual general meeting of the members of the Corporation shall thereafter be held once in every year at such time as may be prescribed by the by-laws for the time being in force, for the election of members of a General Council of members of the Corporation, and to receive annual financial and other reports for the past year and for other purposes of the Corporation, and other general meetings may be held from time to time as occasion shall require and as the by-laws shall direct." Also in the power to make by-laws, which is conferred by the following clause: "At any general meeting it shall be lawful for the members of the Corporation, or such of them as shall be then present, to ordain and make such by-laws as to them or the major part of them shall seem proper for the regulation and good government of the Corporation and of the members and affairs thereof, and generally for carrying the objects for which the Corporation is founded into full and complete effect, with reasonable penalties and fines to be contained in such by-laws on the offenders for non-performance of or disobedience to the same, and the said by-laws, penalties, and fines, or any of them from time to time, to alter, change, or annul as the said members in general meeting shall think requisite, and to mitigate the same as they shall find cause, so as all and singular such by-laws, penalties, and fines be reasonable and not repugnant or contrary to the provisions of these presents or to the laws and statutes of this our realm."

The formation and powers of the General Council and of the Executive Committee, together with details as to voting and the like, complete the draft.

THE SCOTTISH UNIVERSITIES COMMISSION.

ORDINANCE No. 18 has just been issued by this Commission, and embodies regulations for the graduation and instruction of women in the Universities. It applies to the Faculties of Arts, Science, and Medicine, but only the provisions applicable to the last shall be referred to here. Power is given to the University Court to admit women to graduation in such faculty or faculties as the Court may see fit. Power is also given to the Court, after consultation with the Senatus, to make provision within the University for their instruction, either by admitting them to the ordinary classes, or by instituting separate classes for them; and such classes shall be conducted by the professors or lecturers in the several subjects, or by lecturers specially appointed for the purpose by the University Court. It is provided that the Court shall not institute classes where men and women shall be taught together except after consultation with the Senatus, and no professor whose commission is dated before the approval of the Ordinance by Her Majesty shall be required, without his consent, to conduct classes to which women are admitted. The conditions of graduation are to be the same for both sexes, with the following exception, namely, that so long as within the Faculty of Medicine in any University provision is not made for the instruction of women, it shall be in the power of the University Court to admit to graduation women who have received the requisite instruction in any University of the United Kingdom, or in any Indian, colonial, or foreign University recognised for the purpose by the University Court, provided that every candidate for graduation shall produce evidence of having satisfied the conditions with respect to the preliminary examination, and shall be examined in all the subjects necessary for graduation by the examiners of the University in which she takes her degree. As soon, however, as provision is made within the University for the instruction of women in all subjects required for graduation, the conditions of their graduation shall then, even in this respect, be similar to those for men. With reference to women who have begun their studies before this ordinance comes into operation, it shall be competent for the University Court to admit them to graduation in medicine if they complete their medical studies in accordance either with the regulations for graduation hitherto in force, or with the regulations prescribed by this ordinance; while, as regards their studies prior to the date at which this ordinance comes into operation, such women may have obtained their instruction in any classes which the Court may accept for the purpose. Provision is further made that women proposing to graduate must pay the matriculation fee of the University, and power is given to the Court to make arrangements for the use by them of the libraries and museums open to matriculated students of the University

ARMY AND NAVY ESTIMATES.

UNDER Vote A for the establishment of the Regular Army, exclusive of India, we find, grouped under the head of General and Departmental Staff, that the Medical Department (including the Head Quarters Staff) numbers altogether 624. The total of the Medical Staff Corps of all ranks is 2410. The amount of Vote 2, for medical establishment, pay, &c., is £290,100, showing a net decrease of £2700 for the coming financial year. Under Vote 11, for establishments for military education, with an estimated total of £113,500, the cost of the Army Medical School stands at £7084, a small amount compared with that of the Royal Military College and Academy respectively; the estimated expense of the former being £43,635, that of the Royal Military Academy £34,421. From the detailed statement of medical staff it seems that the total numbers, including both British and Indian establishments, amount to 954. In the prefatory explanations of the differences between the amounts proposed in the Army Estimates for 1892-3, and the amounts voted for 1891-2, it is stated that the pay of the medical staff has been over-estimated in past years, insufficient allowance having been made for casualties. The cost of medicines and instruments is expected to decrease in the ensuing year. These estimates are a mine of well-arranged and clearly expressed information on a variety of subjects connected with the public services.

Vote 3 gives the gross estimate for the medical establishments and services for the Navy as £150,530, from which appropriations in aid (£25,530) have to be deducted, leaving £125,000 as the net estimate for 1892-3. There is a net increase of £2300 over last year. The numbers in the medical establishments at home and abroad amount to 111, which include two inspectors-general of hospitals, eight deputy inspectors-general, ten fleet surgeons, six staff surgeons and twenty-seven surgeons, three head sisters and twenty-one sisters, and fourteen dispensers, in addition to chaplains, storekeepers, &c. The total salaries and allowances amount to £35,256, being nearly the same as last year. Among the expenses of the Admiralty Office, salaries, and allowances, £7453 is the estimate for the Medical Department. This sum covers the pay and allowances of a total of seventeen, composed of the Director-General of the Naval Medical Service, a deputy inspector-general of hospitals and staff surgeon, with a clerical establishment.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5866 births and 4469 deaths were registered during the week ending March 12th. The annual rate of mortality in these towns, which had been 23·4 and 20·5 per 1000 in the preceding two weeks, rose again last week to 22·9. In London the rate was 22·1 per 1000, while it averaged 23·4 in the thirty-two provincial towns. The lowest rates in these towns last week were 16·5 in Newcastle-upon-Tyne, 16·8 in Cardiff, 17·8 in West Ham, and 17·9 in Brighton; the highest rates were 28·2 in Blackburn, 30·0 in Liverpool, 31·0 in Halifax, and 32·8 in Swansea. The 4469 deaths included 406 which were referred to the principal zymotic diseases, against 426 and 390 in the preceding two weeks; of these, 170 resulted from whooping-cough, 113 from measles, 48 from diphtheria, 42 from diarrhœa, 15 from "fever" (principally enteric), 13 from scarlet fever, and 5 from small-pox. No deaths from any of these zymotic diseases were recorded in Plymouth, Preston, or Halifax, while they caused the highest death-rates in Birkenhead, Bolton, Liverpool, and Wolverhampton. The greatest mortality from measles occurred in Portsmouth, Swansea, Norwich, Birkenhead, and Liverpool; from whooping-cough in Burnley, Birkenhead, Derby, Bolton, and Wolverhampton, and from diarrhœa in Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the thirty-three large towns. The 48 deaths from diphtheria included 34 in London, 2 in West Ham, and 3 in Manchester. Two fatal cases of small-pox were recorded in London, 2 in Liverpool, and 1 in Oldham; 13 small-pox patients were under treatment in the Metropolitan Asylum Hospitals, and 1 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of last week was 1202, against 1193 and 1190 on the preceding two Saturdays; 117 new cases were admitted during the week, against 86 and 96 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 461 and 379 in the preceeding two weeks, rose again last week to 454, but were 71 below the average. The causes of 88, or 2·0 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Leicester, Leeds, Newcastle-upon-Tyne, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Preston, Halifax, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·8 and 22·5 per 1000 in the preceding two weeks, rose again to 22·6 during the week ending March 12th, but was 0·3 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·0 in Paisley and 17·1 in Dundee to 27·5 in Perth and 28·1 in Aberdeen. The 629 deaths in these towns included 29 which were referred to whooping-cough, 16 to measles, 9 to diarrhœa, 7 to diphtheria, 6 to "fever," 3 to scarlet fever, and not one to small-pox. In all, 70 deaths resulted from these principal zymotic diseases, against 62 and 68 in the preceding two weeks. These 70 deaths were equal to an annual rate of 2·5 per 1000, which was 0·4 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 24 and 19 in the preceding two weeks, rose again last week to 29, of which 19 occurred in Glasgow, 4 in Edinburgh, and 4 in Aberdeen. The 16 deaths referred to measles exceeded by 5 the number in the previous week, and included 15 in Glasgow. The fatal cases of diphtheria, which had increased in the preceding four weeks from 1 to 12, declined again last week to 7, of which 6 occurred in Glasgow and 1 in Aberdeen. The 6 deaths from "fever" were within 2 of the number in the previous week, and included 3 in Glasgow and 3 in Aberdeen. Two of the 3 fatal cases of scarlet fever were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had increased in the preceding three weeks from 146 to 165, declined again last week to 154, and were 47 below the number in the corresponding week of last year. The causes of 53, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 39·5 and 32·7 per 1000 in the preceding two weeks, rose again to 35·5 during the week ending March 12th. During the first ten weeks of the current quarter the death-rate in the city averaged 38·5 per 1000, against 29·9 in London and 19·6 in Edinburgh. The 238 deaths in Dublin during the week under notice showed an increase of 19 upon the number in the preceding week, and included 12 which were referred to measles, 6 to whooping-cough, 2 to diarrhœa, and not one either to small-pox, scarlet fever, diphtheria, or "fever." In all, 20 deaths resulted from these principal zymotic diseases, equal to an annual rate of 3·0 per 1000, the zymotic rate for the same period being 2·6 in London and 1·2 in Edinburgh. The fatal cases of measles, which had been 3 and 7 in the preceding two weeks, further rose to 12 last week, and exceeded the number recorded in any week since September, 1887. The deaths referred to whooping-cough, which had been 8 in each of the preceding two weeks, declined to 6 last week. No fatal case of "fever" was recorded in Dublin last week, the numbers in the previous two weeks having been 7 and 4 respectively. The 238 deaths in Dublin last week included 34 of infants under one year of age, and 71 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded those recorded in the preceding week. Two inquest cases and 3 deaths from violence were registered

Digitized by Google

and 90, or more than a third, of the deaths occurred in public institutions. The causes of 20, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

Inspector-General of Hospitals Doyle M. Shaw, C.B., completes his period of service in charge of the Naval Hospital at Haslar on the 25th inst., and, as already stated, will be succeeded by Inspector-General Mortimer, from the Plymouth Hospital. The vacancy at Plymouth will, it is understood, be filled by Inspector-General W. H. Lloyd.

Surgeon-Captain Hugh Rayner (Grenadier Guards) will accompany, as Medical Officer, the party under the charge of Major Julian J. Leverson, R.E., Her Majesty's Commissioner for the delimitation of British and Portuguese spheres of influence in East Africa. The party leaves Southampton on the 19th inst. by the Royal Mail steamer *Moor*.

Surgeon-Major T. J. Gallwey, M.D., has been appointed Principal Medical Officer of the Egyptian Army.

Deputy Inspector-General G. J. Shaw, M.D., late Bombay Army, and late assay master, Madras Mint, died on the 3rd inst. at Aherlow, Ventnor, aged 73.

We learn from the Navy Estimates that the vote for medical establishments amounts to £125,000, showing an increase of £2300.

ARMY MEDICAL STAFF. — Surgeon-Lieutenant-Colonel Henry Joseph O'Brien, M.B., to be Brigade-Surgeon-Lieutenant-Colonel, vice R. Collins, M.B., retired (dated Feb. 14th, 1892).

NAVAL MEDICAL SERVICE. — The following appointments have been made at the Admiralty:—Staff-Surgeon William Tait, M.B. to the *Nelson*, for temporary service (dated March 8th, 1892). Surgeons: Alfred Cropley and Edward A. Spiller, M.D., to Jamaica Hospital, and Ernest C. Lomas to the *Excellent*, additional (all dated March 15th, 1892).

MADRAS SUBORDINATE MEDICAL ESTABLISHMENT.

A Commission is conferred on the undermentioned Senior Apothecary under the terms of the Royal Warrant of July 19th, 1890:—Senior Apothecary, Second Grade, Chas. Thipthorp (dated July 19th, 1890, but to rank as Honorary Lieutenant from March 21st, 1889).—The undermentioned Senior Apothecaries, Second Grade, will rank as Honorary Lieutenants from the following, dates instead of those given in the *London Gazette* of Nov. 28th, 1890:—Christian Michael Antonio (since deceased), Dec. 22nd, 1889; Jonas Isaac Laffrey, Jan. 11th, 1890; Geo. Edwin King, Feb. 8th, 1890; Jonathan Chadwick, Aug. 28th, 1890. — The promotion of Apothecary, First Grade, Edmund Trutwein, to be Senior Apothecary, Second Grade, ranking as Honorary Lieutenant, notified in the *London Gazette* of Dec. 12th, 1890, is post-dated to Oct. 14th, 1890.—The promotion of Apothecary, First Grade, Chas. Trutwein (since deceased), to be Senior Apothecary, Second Grade, ranking as Honorary Lieutenant, notified in the *London Gazette* of Dec. 12th, 1890, is cancelled.

VOLUNTEER CORPS.—*Rifle:* 1st Nottinghamshire (Robin Hood): Herbert George Ashwell, Gent., to be Surgeon-Lieutenant (dated March 12th, 1892).

THE DRAINAGE OF CAIRO.—The Cairo correspondent of the *Daily News* states that a commission of engineers has sent in a report to Sir Colin Moncrieff on the drainage of Cairo. Sir C. Moncrieff will submit the scheme to the Ministers. The original outlay will amount to half a million sterling. It is proposed to construct huge sewers which will deposit their contents into a reservoir, whence the sewage will be pumped out on to a tract of land.

NATIONAL LEPROSY FUND.—A meeting of the Special Committee of the Fund was held in one of the Conference Rooms of the House of Commons, on the 11th inst., for the purpose of further considering the report of the Commissioners on the results of their investigations in India. There were present the Hon. G. Curzon, M.P., in the chair, Mr. Hutchinson, Dr. George Heron, Mr. C. Macnamara, Mr. E. Clifford, and, in attendance, Sir Somers Vine, honorary secretary of the Fund, and Dr. P. Abraham, honorary secretary of the special committee.

Correspondence.

"Audi alteram partem."

BLOOD CHANGES AND URIC ACID.

To the Editors of THE LANCET.

SIRS,—I should be very glad if you would allow me space for a few remarks on one point in the very admirable lecture of Dr. A. E. Wright in your issue of March 5th, as it has an important bearing on a research in which I have long been engaged. I refer to his remarks on the increased excretion of uric acid, on p. 517, where it appears that he attributes the *plus* uric acid to the nuclein constituent of the tissue-fibrinogen injected; that is, he believes it is due to a *plus* formation of uric acid. Another observer, Dr. Hunter, in his remarks on a paper which I read before the Medical Society in December, on a Case of Raynaud's Disease with Paroxysmal Hæmoglobinuria,[1] urges that the excess of uric acid is the result of the destruction of blood elements, and not, as I in the above paper and in my book[2] have contended, the cause of this destruction. In the case which formed the subject of my paper at the Medical Society I am reminded by my colleague, Dr. Wheaton, that in the blood which he kindly examined after one of the attacks of hæmoglobinuria he found not only great diminution of red cells, but an excess of white cells, and an increase in coagulability. I gave my reasons for believing that an excess of uric acid in the blood preceded and was the cause of these blood changes, the very ones about which Dr. Wright is speaking. I also pointed out that treatment of the uric acid factor produced a remarkable improvement in the case. I am not only prepared to assert that the uric acid is the cause of these blood changes, but I can go further, and show how there came to be an excess of uric acid in the blood.

In my paper on the excretion of uric acid in epilepsy[3] I pointed out that for some hours before the onset of the fits there was a *minus* excretion or retention of uric acid, and I inferred that the *plus* excretion and excess of urate in the blood which came later and produced the fits was the natural and ordinary result of the previous *minus* excretion. It is a very simple matter to alter from hour to hour or from day to day the excretion of uric acid; but whenever there is produced by drugs or diet a retention of, say, five grains of uric acid, there is certain to be at some future time, when the conditions become favourable to its solution in the blood, a *plus* excretion of a corresponding amount. I have pointed out that in epilepsy and in headache the *minus* excretion of urate that precedes the attack is accompanied by mental conditions of happiness and well being, the results of the blood being free from urate, so that if anyone was to argue that the *plus* excretion of urate is the result of the headache or of the fit, I should ask whether the headache or fit began a week ago, because the fluctuation in urate excretion began then. In my experience of epilepsy it is a very common thing to be told that he or she was very bright and well on Thursday, Friday, and Saturday, but on Sunday had six or eight fits; the whole thing is a fluctuation in urate excretion, which produced the fits, but was not produced by them. A similar fluctuation in urate excretion accounts for the periodicity of the uric acid headache, and in the case of headache I have shown (and I believe the same will yet be found to hold in cases of epilepsy) that if the blood is kept clear of uric acid the disturbance of the nervous system does not occur. Now precisely the same thing is seen in paroxysmal hæmoglobinuria—that is, the attack is preceded for days or hours (as the case may be) by feelings of happiness and well-being, and a *minus* excretion of uric acid. In the first case of this disease recorded in my book (p. 212) the symptoms of well-being preceding the attack were specially mentioned by the relatives, and I there give the excretion of urates in other cases during and between the attacks. If the *plus* excretion of the attack is due to a fresh formation of uric acid, why is it preceded by days or hours of *minus* excretion, why does the *plus* excretion of the attack correspond in amount to

Digitized by Google

the *minus* excretion which preceded it? I have been led to argue from these and other facts too numerous to mention here that in paroxysmal hæmoglobinuria the excess of urate in the blood is the cause of the changes that take place in it; but it can, I believe, be proved to demonstration that the *plus* excretion of urate which accompanies these attacks is not their result. Into the observations of Horbaczewski quoted by Dr. Wright I do not here attempt to enter in detail; but I will say that the *plus* excretion noticed by this observer does not seem to me to prove that there was in any of the conditions mentioned a *plus* formation of urates.

I am, Sirs, yours faithfully,

Brook-street, W., March 14th, 1892. ALEXANDER HAIG.

"THE BACTERIOLOGICAL DIAGNOSIS OF DIPHTHERIA."

To the Editors of THE LANCET.

SIRS,—In one of your leading articles in the current number of THE LANCET you comment upon the importance of the recent discussion at the Berlin Medical Society on the pathology of diphtheria, more especially with regard to the part played by Löffler's diphtheria bacillus in its causation. It must have been the experience of all of us that there are cases in which we have suspected the existence of diphtheria, and yet from the clinical characters alone we have been unable to arrive at a diagnosis; for all membranous exudations are not diphtheritic, and, moreover, diphtheria is not always accompanied by membranous exudation. All of us who see much of diphtheria in public institutions or in private are ready to welcome any bacteriological method by means of which, as in the case of the tubercle bacilli, we may make a certain diagnosis.

During a recent visit to Berlin I was enabled, through the kindness of Dr. A. Baginsky and his assistants, to watch the cases in the diphtheria pavilion of the Kaiser und Kaiserin Friedrich Kinderkrankenhaus, and to see the methods in use in the laboratories attached to that institution. The children admitted to the diphtheria pavilion were in the first place received into a special ward for twenty-four hours, during which time cultivations were made from the membrane or exudations taken from their fauces, and they were then either admitted to the general ward if the diphtheria bacillus was found, or to special wards if only streptococci or non-pathogenic micro-organisms were detected. I came away impressed with the value of the bacteriological diagnosis of diphtheria when the investigations were conducted by trained hands, and where it was possible not only to cultivate the bacilli, but in doubtful cases to test the correctness of the histological diagnosis by injecting a portion of the culture medium into guinea-pigs. Dr. Baginsky himself was sanguine enough to believe that before long this method will be practised by every general practitioner in Germany. You have pointed out the difficulties in the way of this as regards the time and skill required, and these difficulties must always be especially felt where it is impossible to resort to the inoculation of animals to confirm results. Nevertheless, I am inclined to think that much valuable aid may be rendered in the way of diagnosis by the microscopical examination of the exudations in suspected cases of diphtheria, and still more by cultivation if time and opportunity are afforded. In most cases cover-slip preparations of the exudations from diphtheria will, if properly stained, show the bacilli readily enough, and they can be recognised without difficulty. In this way I have been able to diagnose diphtheria from an examination of the nasal secretion and the sputa coughed up in patients where no membrane was found till some time later. The chief difficulty which meets us here is the different size and shape which the diphtheria bacillus presents according to its age and the circumstances of its growth. It stains well with carbol-fuchsine or Löffler's pot. methylene blue, but so do all sorts and conditions of micro-organisms, and we are dependent entirely for its recognition upon its morphological characters. The typical bacillus of diphtheria is thick and short, often slightly curved, found singly, but more often joined together in twos or more. In the older forms it is thicker and darker at the ends than in the centre. But even in pure cultivations forms may be seen which do not present typical characters, varying in size, and in some instances being shorter, so as to be almost indistinguishable from diplococci. It is certain we cannot depend on the morphological characters alone for their diagnosis in all cases. The difficulty does not always end when cultivations are made on blood serum; the colonies are not always characteristic, and a microscopical examination may still leave us in doubt, unless typical forms are present. These difficulties no doubt are lessened as experience increases, but that they are real difficulties I know by experience. It is certain that through the researches of Löffler, Escherich, Heubner, Baginsky, and others in Germany, and Roux and Yersin in France, an important addition has been made to our knowledge of the pathology of diphtheria and our methods of diagnosis, and if there are still difficulties in the way, we are not without hope that they may be overcome.

I am, Sirs, yours truly,

Manchester, March 13th, 1892. HENRY ASHBY.

THE ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—The several admirable and exhaustive leading articles which have appeared in the columns of THE LANCET on the recent action of "Steele *v.* Savory" seem to me to leave little room for further argument. The committee of the Association of Members fully deserve, as you have so well said, to be credited with the courageous effort made to serve the general body of the Members of the College; and it is scarcely possible to believe that anyone who has looked into the facts will deny this, much as he may disapprove of the legal proceedings. But this difference of opinion cannot be assigned as a reason why the expenses incurred should be defrayed by the few who have stood in the breach and thereby happen to appear the more immediately responsible. A considerable amount of difficulty, however, presents itself in any attempt to bring home this truism to the minds of the 10,000 or 12,000 Members of the College, most of whom must have felt more or less interest in the work in which the Association of Members have been engaged. I therefore venture to ask permission to occupy a small space in your columns to make it perfectly clear that the committee have invariably acted under the advice of counsel, and to the best of their ability in the interests of Members, and feel that they may confidently appeal to the 4000 Members who appended their signatures to the petition presented to the Privy Council some three or four years ago. A small contribution from each one of them will be sufficient to meet the legal expenses incurred on their behalf. The large body who supported the Association of Members at this period showed at least that they had the courage of their opinions; and it is impossible to believe that a profession proverbial for its generosity and open-heartedness will withhold its sympathy from those of their brethren "who have fought the battle and find themselves burdened with costs amounting to £2000." In your words, Sirs, I hope and trust "the Members for whom the struggle was commenced will respond to the appeal of Dr. Danford Thomas, the treasurer, and by their prompt and generous assistance testify to the courage and self-abnegation displayed in the important contest in which the plaintiffs were engaged on behalf of the members generally."

I remain, Sirs, your most obedient servant.

Bedford-square, March 15th, 1892. JABEZ HOGG.

POST-MORTEM APPEARANCES OF THE BRAIN OF INFLUENZA PATIENTS.

To the Editors of THE LANCET.

SIRS,—I have read with much pleasure and satisfaction the important statement which appeared in THE LANCET of March 12th, from Dr. Macdonald, who has, as far as I am aware, been the first to discover and to demonstrate the special lesion which I have been led to consider as productive of the feverish attack of grip. It was in the hope of eliciting such information as Dr. Macdonald has given us that I started, with your permission, the discussion on this subject which has been going on in THE LANCET. There can be no doubt that what Dr. Macdonald has found in one case must have been present in a great many others, but was overlooked because no special attention was given to it. I confess that I do not quite understand why Dr.

Digitized by Google

Goodall should show himself so anxious to repudiate the existence of characteristic lesions in the brain of gripped patients. If he has read my paper on the neurotic aspects of influenza, which appeared in THE LANCET of Nov. 14th and 21st, he surely must concede that I have made out at least a *primâ facie* case for the existence of a bulbar lesion as the material base of the phenomena witnessed in the feverish attack. Let me remind him that Adams of Cambridge deduced the existence of Neptune from symptoms of disturbance seen in the movements of neighbouring celestial bodies, and that, after this idea had been duly ridiculed by the authorities at Greenwich, the planet was discovered by the French astronomer, Leverrier, in the exact position which the English *savant* had predicted. An analogous case in medicine is that of labio-glosso-laryngeal paralysis, the focal lesion of which was predicted by Wachsmuth in 1864, and shown to exist by Charcot in 1870. I can therefore claim good precedents for the course I have taken in this matter.

Dr. Goodall is dissatisfied with the meagre account of post-mortem appearances extracted by me from Maillard's work. I feel inclined to reply that half a loaf is better than no bread, and that I am not responsible for Maillard not having been more explicit, but as Dr. Goodall has indulged in an apparently destructive criticism of the cases brought forward, I will, with your permission, follow in his track, and endeavour to "pulverise" him in turn. Due regard for your space, however, must limit my remarks to the first two cases in question. Commenting on the first case, Dr. Goodall seems to be very much annoyed that the lesions should have been limited to the cerebellum, and states that "we might at least have suspected hyperæmia elsewhere." He also insinuates that the appearances noted—viz., hyperæmia, hæmorrhage, and softening—might be rather due "to a fit of sneezing or coughing than to any such theoretical cause as that suggested." In reply to this, I may mention that the subject of the case was a domestic servant, aged twenty-five, who was in perfect health ("en parfaite santé") at the time she was seized by influenza. Unfortunately for Dr. Goodall's startling suggestion that hyperæmia, hæmorrhage, and softening of the cerebellum in a young woman who was in perfect health might be owing to sneezing or coughing, she never sneezed or coughed at all during her short illness (three days). It happened to be a case of the so-called "gastric form" of influenza, beginning with most distressing vomiting, which was shortly followed by grinding of teeth, violent headache, incessant agitation, and later on by coma. The "sneezing and coughing" theory, therefore, falls absolutely to the ground in the present instance. In the second case Dr. Goodall can see "no bearing of the bursting of an aneurysm of the basilar artery upon the pathology of influenza." May I therefore be allowed to remind him that the bulb receives a vascular supply from the basilar artery, and that intense congestion of that vessel during the attack of grip may have led, first, to the giving way of the internal and middle coat of the artery, and, finally, to rupture of its external coat? The history of the case renders such an explanation highly probable. The patient was a man aged forty-seven, having no neurotic, alcoholic, or syphilitic antecedents, and who had been in good health, with the exception of having had typhoid fever and bronchitis some time previously to becoming gripped. He had two attacks of influenza, the principal symptoms of the first being severe pain at the back of the head, vertigo, and tinnitus, from which he had never suffered before. Now Dr. Goodall knows as well as myself that the basilar artery gives branches, not only to the bulb, but also to the membranous labyrinth, and that the vertigo and tinnitus are therefore most significant symptoms in connexion with the formation of the aneurysm of that artery, which, I take it, occurred during the first attack of grip. The patient, although he recovered from the first feverish attack, never felt well afterwards, and had a second attack three months later. The first symptom was, once more, vertigo; he fell down, and remained unconscious for half an hour. After coming to he complained of severe pain in the head and all over, of tinnitus, vertigo, impaired sight, and had a pulse of 50 beats in the minute—all signs of irritation in the sphere of the basilar artery. Two days afterwards he suddenly fell out of bed, and died—of course, from the rupture of the aneurysm. Surely there never was a clearer or more logical sequence of events. I now take leave of Dr. Goodall, in the hope that he may yet come round to my view of the subject, and that he may give us at some future time, not barren criticism, but positive contributions to our knowledge in the way Dr. Macdonald has done.

I am, Sirs, yours faithfully,

Harley-street, March, 1892. JULIUS ALTHAUS, M.D.

ETHER AS A STIMULANT AT THE TEMPERANCE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—With regard to your homily to the staff of the Temperance Hospital, it would be well if you had made sure of your facts first. The anonymous correspondent has misled you. Nearly all the ether used therein has been used for anæsthetic purposes; a small quantity has been used externally, and a very little has been administered subcutaneously in rare emergencies. I am not aware that any has been used internally, and for the very good reason that ether is only soluble in alcohol, and there is not a drop of spiritus etheris on the premises. So much for the mare's nest. But your article shows a complete misapprehension of the object of the Temperance Hospital. It is admitted that some people (probably many) have acquired a craving for drink through having been ordered to take some common form of alcoholic beverage; it is also a fact that some reformed drunkards have had their desire for alcohol reawakened through being ordered beer, wine, or spirits during illness; and it is notorious that a large number of people think that some form of alcoholic liquor is absolutely necessary for the cure of most diseases, exceedingly useful in nearly all the rest, and especially valuable during convalescence as a tonic and "strengthening" agent. It is also thought that a remedy which is so valuable to cure disease must be equally useful to ward it off. Alcoholic liquors are still largely recommended and relied on by a great many medical men, and were still more when the Temperance Hospital was first established. Its object, then, is to show that the ordinary use of alcohol is totally unnecessary, and thus to check the spread of the alcohol habit. But we can avoid, and have avoided, that. It would be equally absurd to reject ether because some have taken excess in the north of Ireland as to abandon the medicinal use of opium because opium is a common curse in China. If I were practising among ether or opium drunkards I should avoid the use of these medicines as much as possible. If alcohol had never been taken save in medicine, and had only been dispensed as a drug, there would have been no great drink question urgently demanding solution. Such a use of alcohol would be harmless, but at the Temperance Hospital we have shown that even when alcohol might be useful it is possible to employ something else. Our experience proves that its value is grossly exaggerated, and that its total disuse would not render the cure of disease more difficult. You are also probably aware that the special legislation which has put an end to ether drinking in Ireland is an order scheduling ether as a poison, only to be procured as other poisons are. We shall be quite content when alcohol, which has done infinitely more harm than ether, is treated in the same way.

I am, Sirs, yours truly,

J. J. RIDGE, M.D. Lond.,

March 12th, 1892. Physician to the London Temperance Hospital.

THE EFFECTS OF INFLUENZA UPON THE MIDDLE EAR.

To the Editors of THE LANCET.

SIRS,—My limited experience as a country practitioner has been so strangely opposed to that of Sir W. Dalby regarding the effects of influenza upon the middle ear that I venture to ask your permission to draw attention to a case in which a very serious ear complication supervened upon an attack of influenza in a patient who had previously no ear troubles of any kind. This man came under my care in the spring of 1890. He was apparently in a fair way to recovery from this disease when he was suddenly seized with acute pain in the left ear. The influenza attack had run quite a usual course and was not of a very severe type. The temperature had been normal for a few days before the ear trouble began. With the view of relieving the pain I ordered hot applications in the way of fomentations and

Digitized by Google

poultices, with the result that shortly a free discharge of pus escaped from the meatus. Relief followed, and the patient appeared better. The discharge continued to be free and abundant for a few days, when it became much scantier, and then disappeared almost completely. The result of this was that the patient began to complain of intense pain in some of the joints, more especially the knees. The temperature went up to 104° F., and the case had now all the appearances of rheumatic fever, but in view of the previous history one could not help associating the condition of the joints as well as the pyrexia with the stoppage of the discharge from the ear. With the renewed application of moist heat to the ear and the internal administration of salicylate of soda the discharge became more abundant, the pyrexia became less, and things looked generally more favourable, until a few days subsequently it was noted that there was considerable swelling, and some slight redness over the mastoid. The general condition of the patient was now not at all satisfactory. There were great anorexia, extreme debility, great pallor, and the discharge from the ear was not as abundant as one would have liked under the circumstances. In view of this state of matters, I became anxious to have a further opinion upon the case, and I determined to take the patient at once to see Mr. Richard Williams of Liverpool. Mr. Williams was impressed with the gravity of the case, and advised that the mastoid should be thoroughly dealt with. He proposed to cut down freely upon it, and if necessary to gouge the bone, and then to pass a drainage tube into the opening thus made and bring it out through the external meatus. On the following morning the patient was put under chloroform, and Mr. Williams dealt with the case precisely as stated above, with the exception that the drainage-tube was not passed through into the external meatus. A considerable amount of pus escaped when the incision was made, the mastoid was gouged, and the diseased portion thus removed. A drainage-tube was inserted and the wound stuffed with antiseptic dressing. The improvement in the condition of the patient after this radical form of treatment was most marked in two or three days. The appetite returned, the pallor diminished, and the wound steadily healed up with healthy granulations from the bottom, and the discharge became gradually less, until in a very short time it disappeared completely. Within a few weeks the wound was completely closed, the hearing power was returning and slowly improving, and in the course of a few months the patient was as strong as ever and the hearing excellent on the affected side. This is the only case in my experience during the epidemic in which the mastoid became so seriously affected, and the general condition so grave in consequence; but I met with a considerable number of cases of influenza in which there supervened during convalescence great pain in the ear, followed by a purulent discharge therefrom, in persons who stated that they had previously no ear troubles of any kind, and who thus corroborated the experience recorded in THE LANCET of March 5th by my old teacher, Dr. Walker Downie of Glasgow.

I am, Sirs, yours faithfully,

HUGH JONES, M.B.,
Late Resident Physician, Glasgow Western Infirmary.

Dolgelly, North Wales, March 14th, 1892.

"THE FUTURE OF THE HUMAN FOOT."

To the Editors of THE LANCET.

SIRS,—This, as Mr. Clement Lucas tells us,[1] "would appear to be a gradual suppression from without inwards of the toes, and a further strengthening of the great toe line on the inner side. That this is all that is required is abundantly proved by observing the thousands who, even at the present time, use only the great toe as a means of progression." Kindly permit me to point out how remarkable it is, if this be true, that we do not find proof of it in hypertrophy of the muscles acting on the great toe, and in atrophy of those acting on the smaller ones. These latter move together each of them in the same vertical plane, and, even when closely packed against each other, may be firmly pressed downwards in every step. That such is commonly the case it would be easy to prove. The great toe, on the other hand, having as its position of rest an inclination upwards and outwards over the second toe, moves downwards and inwards away from the others. *It* is clear that when fixed in the median-pointed boot the great toe cannot so move, and that the joint surfaces, which are prevented from following the course for which they are adapted, either do not move at all or do so only with irritation to the structure. And I venture to assert that if anyone will examine a large number of feet, as I have for many years been doing, he will find evidence of defect of function in the great toe more often than in the smaller ones. I except the little one, but cannot admit that even it, poor thing though it seems, is "useless." The metatarso-phalangeal joint of and the muscles acting on this toe are generally found to be in working order, and even when it consists of a continuous bone only, I maintain that it still coöperates with its fellows in relieving the pressure which falls on the heads of the metatarsal bones as the heel is uplifted and the body propelled onwards from the front part of the foot. Nor do I believe that it is "fast disappearing," hardly used though it be. A stunted form of it, I may remark, was an ideal, if not a reality, when the Venus di Medici was chiselled. I do not disparage the great toe. Seventeen years ago I wrote of it that "there is no more marked distinction between man and the lower animals." Then and ever since I have persistently enforced in THE LANCET (Feb. 9th and June 30th, 1884, and Sept. 25th, 1886) and elsewhere the importance of its functions. I plead only now that the smaller toes are also important and not likely to be effaced.

What "the future of the human foot" is to be will depend, to some extent, on how those who, in the present, have to advise with respect to its use and to the prevention of troubles arising from misuse. For myself, I regard it as an organ of the body having its own proper physiology, as definite as that of the eyeball, so that to speak of the joint at the base of the great toe as not equal to the strain upon it, while its functions are almost always exercised under conditions involving irritation, seems to me to be unfair. Moreover, I cannot without regret observe that Mr. Lucas continues to associate a common deformity (flat-foot) with "immoral practices"—he has spoken more plainly elsewhere.[2] It is really due, as I contend, to defect of function, and, as I know, it can, by renewal of function, be repaired. Anyway, the wide prevalence of it, in varying degree, among all classes, in both sexes, and at nearly all ages, appears to me to forbid, for the present, the prediction of "a further strengthening of the great toe line" as a prospective development.—I am, Sirs, yours faithfully,

Gloucester, March 4th, 1892. T. S. ELLIS.

HEREDITARY SUPPRESSION OF FINGERS.

To the Editors of THE LANCET.

SIRS,—Mr. Clement Lucas, in his interesting paper on Suppression of Digits in THE LANCET of the 27th ult., refers to the frequent occurrence of contracted little finger, accompanied by contraction or malformation of the toes. This subject has received some attention of late from Mr. Adams[3] and Mr. Anderson,[4] but I believe that the occasional association of contracted little finger with hammer-toe was first pointed out by my friend and colleague, Mr. Fisher, in his article on the treatment of deformities in the "International Encyclopædia of Surgery." Mr. Lucas attributes this not very common deformity of the little finger and the commonly ill-grown little toe to the same cause—the fact that they are not wanted. Now, Sirs, I venture to think that, however well we may get on without a little toe, thanks to the highly artificial circumstances of the foot in most civilised countries, those of us who use our hands would miss the little finger very much indeed were it to be removed, and so far from expecting this digit to disappear I should expect, if usefulness and evolution are related, that it would become more developed rather than less, for the civilised man (such, for instance, as the musician) uses his fingers independently of each other more than does the savage. I am inclined to the belief that the little toe is well formed in most newborn children, but that the early and continuous use of boots prevents its growth and development. If, however, it be in course of elimination as a useless appendage, I

Digitized by Google

should like to ask Mr. Lucas whether he would explain this as the effect of design, or on the Darwinian hypothesis that the individual with an ill-formed little toe has the best chance in the struggle for life; or would he, following Lamarck, attribute its suppression to the hereditary transmission of an acquired peculiarity.

I am, Sirs, yours truly,

Park-street, W., March 2nd, 1892. E. MUIRHEAD LITTLE.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THE annual meeting of the governors of this hospital was held on the 16th inst., the mayor, Mr. Lawley Parker, being in the chair. The 112th report was read, in which it was shown that the total number of patients was: In-patients, by ticket, 548; without ticket—i.e, accidents and urgent cases—3529; out-patients, by ticket, 14,153; without tickets—i.e., accidents and urgent cases—34,105; total number, 52 335. The total income from all sources has been £18,181 19*s* 3*d*.; the deficiency in the funds, which at the beginning of the year amounted to £6073 1*s*. 8*d*., has, thanks mainly to the receipt of £5000 from the musical festival, been reduced to the amount of £2458 6*s*. 8*d*.—a fact which the committee regard as a matter for sincere congratulation. The Earl of Dartmouth was elected president for the ensuing year. A meeting of the general committee was held on the 8th inst. to receive the report of the building committee upon the competitive plans, and to select the architect for the new building. There were twelve competitors. The committee, with Mr. Waterhouse, R.A., as consultant, recommended three plans for the prizes of £150, £100, and £50 which had been offered. The first prize was unanimously awarded to Mr. William Henman, who has already done good work in various parts of the country.

The Jaffray Suburban Hospital.

The committee have just issued their sixth annual report. During the year 208 patients had been treated. The average stay of the patients in the hospital was fourteen weeks. The epidemic of influenza interfered with the working of the hospital, the matron and several of the nurses having been affected. Twenty-four patients had been treated according to Koch's method for tuberculosis, and generally the utility of the hospital according to its objects had been fully maintained.

The Athletic Institute.

This new institution is vigorously pursuing its work, and already doing much good. "Purity of life in relation to athletic vigour" was the subject of a lecture given on the 10th inst. by Mr. C. G. Wheelhouse. A large and attentive audience listened to this discourse, and frequently showed their appreciation of the lecturer's remarks by the applause given. The next of the series is to be given by Sir Dyce Duckworth, on the "Value of Athletic Exercises as Counter-agents to Sedentary Pursuits." The series embrace a number of free lectures which the Council has been able to arrange by the kindness of the President, Mr. H. Mitchell. The institute will doubtless become popular and useful in promoting exercises and amusements conducive to health and interest.

The Water Scheme.

The attention of our rulers still continues to be given to the solving of this great problem. The expenditure involved in the proposed new supply involves some six millions of money. No wonder that some economists and captious critics view with alarm this enormous outlay. Alternative schemes have been mooted and some opposition raised to the original plans. The need of providing for the future supply of the city is the paramount necessity which governs the action of those who know most about it, and it is more than probable that Parliament will sanction the undertaking as at present propounded. The suffering ratepayer will have to sacrifice his sentiments and his pockets to the general good of the community, and continue his grumblings as heretofore.

March 16th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle Convalescent Society.

THE annual meeting of the Convalescent Society for Newcastle and for the counties of Northumberland and Durham has been held. Dr. Philipson submitted the report for the thirty-second year of the association, which showed that the admissions to the Prudhoe Memorial Convalescent Home at Whitley would bear favourable comparison with those of previous years. The number admitted in 1891 was 1495. The total number of patients admitted since the institution was opened in 1869 was 23,217, of whom over 95 per cent. received benefit.

Diphtheria in Durham County.

Owing to the late epidemic of diphtheria in the Aycliffe district of the Darlington sanitary authority the Local Government Board have requested the authority to instruct the medical officer for the district (Dr. Hardy) to prepare a report on the outbreak, in which he says that there were fifteen cases up to Jan. 15th, of which six proved fatal. Several scholars had suffered from sore-throat, and when seen were affected with paralysis. After the school was closed there were no more cases, but on its reopening fresh cases occurred, which he thought pointed to the school as an infected centre. On inspection of the school nothing amiss was found. I mentioned in a previous note the outbreak in the Houghton-le-Spring sanitary authority, which has now in most part subsided. In order, as far as possible, to prevent a fresh outbreak or a continuance of the disease, all the school books, maps, &c., to the value of about £120, have been burnt.

Newcastle Health Society.

The lectures under the auspices of this Society have been continued, Dr. J. W. Smith's subject being "The Nature of Disease and the Purpose of Medicine." Mr. Frederick Page, I believe, finished the course for the session last Saturday, his subject being "Human Parasites in relation to Food and Disease." The lectures have been very well attended.

Middlesbrough.

Middlesbrough has again made a feature of its Hospital Sunday, the processions to the various places of worship being headed by the mayor, members, and officials of the corporation. The Durham Rifles and other volunteers attended, also the Tees Submarine Miners. The collections were for the North Riding Infirmary and the North Ormesby Cottage Hospital.

Important Accident Assurance Case.

At the Carlisle Assizes last week an action was brought by a widow, and was decided in her favour, involving some very fine medico-legal points. Her late husband had taken out a policy, one of the conditions being that the deceased was suffering from no physical infirmity which rendered him peculiarly liable to accident. Now the deceased had lost an eye twenty years previously from an explosion, and the Lord Chief Justice held that the company could not repudiate their liability, as the loss of the eye must have been obvious to the agent of the company. The deceased met with another accident by which he lost the other eye, and from the effects of which he ultimately died. The widow stated that no conditions were read over to him when he made the assurance proposal, and that if they were he could not understand them, or do more than sign his own name. The jury returned a verdict for £500, and his lordship refused to grant the stay which was applied for.

Interesting Hospital Cases.

I have seen a case in the Royal Infirmary in which Mr. Frederick Page performed Mikulicz's operation (in a patient suffering from chronic dilatation of the stomach) on the 2nd inst. So far the case is doing well. I believe there is no record of this pyloro-plastic operation having been done in this country before. Mr. S. Macaulay has a curious case of objective tinnitus at the Newcastle Throat and Ear Hospital, which I have also seen. The patient is a little girl aged nine, who has not suffered from any other affection of the ear. On listening with the unaided ear a cracking sound is heard, such as would be produced by cracking the

Digitized by Google

finger nails. The affection has lasted three months, and has not been mitigated even by treatment, including persistent Politzerisation &c. At the Sunderland Infirmary an inquest has been held on a boy aged six, who had been admitted for a burn which was shown not to have been the direct cause of death; but a necropsy disclosed extensive liver disease, caused in all probability by alcohol, as it was proved that his mother and his "granny" were in the habit of giving the boy small quantities of spirits extending over a long period. The jury came to the conclusion that the child had died from diseased liver, brought on by alcohol and want of proper nourishment. The coroner also admonished the father of the child.

The Funeral of the late Dr. Heath of Newcastle.

On Thursday last the remains of the late Dr. Heath were interred in Jesmond Old Cemetery in this city, with every manifestation of regret and respect from the profession and our general citizens. Although a blinding snowstorm came on before the funeral, the attendance was very large and representative. The procession was headed by students from the college in caps and gowns, numbering about one hundred; the members of the College of Medicine also of the College of Science, likewise in their robes, joined in, and a large number of country practitioners, old friends, and students. The floral tributes sent to Dr. Heath's memory by all classes were very beautiful and numerous. Dr. Heath at the time of his death was the oldest commissioned officer in the Yeomanry Corps, as surgeon-major. Sergeant-Major Forbes, representing the Northumberland Hussars, followed the remains.

Newcastle-on-Tyne, March 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Liability for Selling Unsound Fish.

IN Edinburgh within the past few weeks there have been one or two prosecutions for exposing to sale unsound fish. The prosecution has now been extended from the retailer of the fish to the auctioneer who sold them, and the sheriff has decided against the auctioneer, his contention being that the sections of the Act were framed to put down the traffic in unwholesome food, and he was of opinion that they were intended to reach every person through whose hands such food passed. This is an important decision, and, if it remains unquestioned, it will be an additional check of great efficacy in diminishing the admission of unsound fish at all events into the retail market patronised by the poorer classes.

Meat Inspection in Edinburgh.

It was mentioned in these columns that the Public Health Committee of the Town Council had proposed the establishment of clearing-houses for the inspection of all meat to be sold as food. The report containing this proposal has been before the Town Council, and meanwhile it has been decided to be content with the appointment of inspectors.

The Edinburgh Maternity Hospital.

The annual meeting of this hospital was held last week, the Lord Provost presiding. During the year 307 patients had been treated in the wards, and there had been 561 outdoor cases. During the year forty-one nurses had been trained. The expenditure was only £864 17*s.* 1*d.* The chairman commented upon the amount of work done for such a small sum, and thought the hospital must be conducted too economically.

Edinburgh Medical Missionary Society.

The jubilee of the Edinburgh Medical Missionary Society was held at the end of last and the beginning of the present week. Religious services of various kinds have been held, in which various eminent persons have taken part, including Archdeacon Farrar.

The winter session of the Edinburgh medical classes will end on Friday of this week. Next week the first professional examinations will begin, and the second professional the week following.

March 15th

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Banquet at the Royal College of Surgeons.

MR. H. GRAY CROLY, J.P., President of the College, gave a banquet in the Museum on Monday evening, the 14th inst., in celebration of the first biennial presidency of the College. His Excellency the Lord Lieutenant and a distinguished company, numbering nearly 200 guests, were present at the banquet. The President, in proposing "The Medical Licensing Bodies," referred to the expenditure of several thousand pounds in improving the schools attached to the College. He availed himself of the occasion, he said, to enter a public protest on behalf of the College of Surgeons and the College of Physicians against the attempt now being made to set up a degree granting monopoly for the benefit of London hospital students. They should not think of interfering with London in this matter if Irish students and teachers were afforded by this proposed university a "fair field and no favour." If the opportunity to show cause against the new Gresham University Charter were afforded they would be prepared to offer arguments which would satisfy the Government that no such monopoly of power to dispense medical degrees ought to be accorded to London or any other teaching centre.

Abolition of Visiting Physicians to Irish Lunatic Asylums.

A new rule which came into operation on Dec 31st, 1891, is to the effect that for the future when any vacancy shall occur in the post of visiting physicians or apothecaries it shall not be filled up. This regulation has caused considerable dissatisfaction, and last week the governors of the Cork District Lunatic Asylum passed the following resolution:—"That we, the governors of the Cork District Lunatic Asylum, entirely disapprove of the new rule dispensing with the services of visiting physicians throughout Ireland, and that copies of this resolution be sent to every asylum board in Ireland." This regulation has been adopted at the suggestion of the inspectors of lunatic asylums, who recommend that in cases of special difficulty the medical superintendent may be empowered to obtain assistance from a specialist in ophthalmic and obstetric affections.

Health of Dublin in 1891.

The births numbered 9850, and the deaths 9195, or 26·3 per 1000. Both the birth- and death-rates were below the average for the previous ten years. Zymotic diseases amounted to 865, or 390 below the average for the ten years 1881–90. To measles only 5 deaths were ascribed, and it is a remarkable occurrence that of 163 cases treated in hospitals during the year not one proved fatal.

Cork District Lunatic Asylum.

From the report for the past year it appears that 1305 patients were treated during the year, of which number 100 were discharged recovered, 45 improved, 27 not improved, 1 escaped, and 69 deaths took place.

A respectable farmer, named Devlin, died on Sunday in Tullyvaughan, co. Tyrone, at the advanced age of 102 years.

March 15th.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

Banquet in Honour of Professor Charcot.

ON the 5th inst., at the Restaurant Durand, the establishment rendered famous as the electioneering headquarters of the late General Boulanger, the former *chefs de clinique* and *internes* of M. Charcot celebrated their renowned chief's promotion from the rank of *officier* to that of *commandeur* of the Légion d'Honneur. The hosts numbered thirty-five, and included such well-known personages as Cornil (year of service 1863), Bouchard (1864 and 1866), Bourneville (1868), Joffroy (1869), Debove (1871), Raymond, Pitres, Brissaud, Ballet, Féré, and J. B. Charcot, the guest's son. At dessert the professor's senior *interne* (Professor Cornil) rose and, in proposing the toast of the evening, depicted in eloquent terms the arduous existence led by the eminent neurologist and his first pupils in the old days when the now celebrated École de la Salpêtrière was only in embryo. So touched was M. Charcot

Digitized by Google

by the terms of the speech that he could not refrain from embracing the orator. Similar speeches having been delivered by M. Joffroy and Professor Pitres of Bordeaux, the distinguished guest returned thanks, and terminated his remarks by urging the younger members of the company to follow in the footsteps of his older pupils, and to drink to the continued prosperity of the Salpêtrière school.

The Civil versus *the Military Element at the Lyons Faculty.*

On the 7th inst. Professor Morat commenced a six months' course of physiology at the above-mentioned Faculty before an audience of 300 students. On his entrance into the theatre the professor was greeted by a volley of hisses, and such articles of consumption as potatoes and eggs—the latter being in various degrees of decomposition—were freely hurled at his devoted head. The unpopular lecturer stood to his guns for half an hour without succeeding in making his voice heard, and then discreetly beat a retreat. What was the head and front of M. Morat's offending? To enable your readers to understand the situation I must explain that there exists at Lyons, besides the Faculty, a Military School of Medicine, the students of which latter establishment being obliged to follow M. Morat's lectures, while such attendance is optional for the civilian students of the Faculty. The professor, perhaps not unnaturally, resents the consequent neglect undergone by his educational efforts at the hands of the civilians. The alleged favouritism enjoyed by the *pantalons rouges* has excited considerable ill-feeling between the civil and military students, the animosity culminating in a scene of violence at the Hôtel Dieu, where Professor Poncet had to separate the combatants. The Council of the Faculty decided to temporarily suspend the lectures, and the doors of the Faculty remained for some days closed to students of medicine, only students of the Faculty of Sciences being allowed to enter. The dissatisfied civilians took advantage of the interregnum to hold a mass meeting, at which there were passed resolutions claiming (1) equal privileges for civilian and military students; (2) the granting to civilian students of a choice of wards for clinical studies—a favour now accorded to the soldiers only; (3) the right to re-present themselves, like the military section, for examination within two or three weeks after a failure; (4) permission to attend night accouchements at the Charité Hospital, a privilege now enjoyed only by the military students; (5) the separation of the civil from the military students at special clinics; (6) an apology from the military student who struck a civilian at the Hôtel Dieu; (7) the exclusion of M. Morat from examining boards, and his replacement as a lecturer by a sub-professor. I understand that the gates of the Faculty have been reopened, but it remains to be seen if the drastic remedies embodied in the above resolutions will be adopted by the authorities. Students are proverbially sensitive, and apt to resent what they consider, often wrongly, to be an injustice. Thus at the Paris Faculty M. Gariel, the Professor of Physics, has incurred the wrath of first year students by his alleged severity as an examiner. Every year these young men are in the habit of celebrating the conclusion of the chemistry and physics classes by a *monôme*. This function, which consists in a procession along the boulevards of men marching in Indian file and holding on to each other's coat-tails, was indulged in the other day by 300 students, who, starting at 11.30 P.M. from the Hôpital St. Louis, made their noisy way towards the Quartier Latin. The cries indulged in were "*Conspuez Gariel!*" and "*Vive Blanchard!*" the last-named gentleman being a *sympathique* sub-professor, who has shown himself less critical of the attainments of more or less apprehensive candidates for examination than the perhaps too conscientious Professor of Physics. The *monômists* were dispersed by a squad of police, who were lying in ambush at the Prefecture, but the manifestation was resumed before the Faculty of Medicine.

Strontium Salts in Therapeutics.

In this country these salts have recently come greatly into favour, and seem destined henceforth to take an important place in the treatment of disease. Their therapeutic efficacy, when they respond to that paramount essential, purity of composition, would appear to be an established fact. Though hardly new to therapeutists, they are unquestionably so to therapeutics, for hitherto their frequent admixture with poisonous or deleterious substances, such as barium and other impurities, has greatly militated against their admission amongst our pharmaceutical resources. Thanks, however, to the patient investigation of Paraf-Javal, a means has been discovered of producing perfectly pure salts, and the use of such salts shows that previous ideas as to the toxic properties of strontium compounds were erroneous, and that toxic symptoms, when manifested, are in reality to be attributed to the impurities hitherto inseparable from these preparations. According to the testimony of such well-known authorities and clinical observers as Germain Sée, Dujardin-Beaumetz, Constantin Paul, Bucquoy, &c., the superiority of the lactate of strontium, when prepared after the process of Paraf-Javal, in the treatment of albuminuria, would appear to be established over all other medicaments. Again, the researches of M. Féré, in his wide field of clinical observation amongst the mental cases at the Bicêtre Hospital, have led him to the conclusion that the bromide of strontium can, in very many cases, be with advantage substituted for bromide of potassium in the treatment of epilepsy. He found that when the bromide of potassium was, from one reason or another, badly borne in doses large enough to be efficient, as often happens, the bromide of strontium was readily tolerated, showing no toxic effects, and with results equal, if not superior, to those obtained by the former salt. M. Laborde, at a recent meeting of the Therapeutic Society, while dwelling on the foregoing facts, impressed on his hearers the necessity of administering pure preparations only, and of avoiding unstable compounds of this element, such as the iodide of strontium, on which experimental pharmacology had not as yet pronounced.

Petroleum in Diphtheria.

At a recent meeting of the Academy of Medicine in Brussels M. Maison, for M. Larcher, read an interesting paper on the highly successful use of crude petroleum in diphtheria. Since 1886 M. Larcher has treated forty-two cases of this disease in this manner, and with only two deaths. Of these two, one was a very young child, which came under treatment at a very advanced period of the malady; the other being a little girl of six, with very extensive disease, who proved so intractable that it was almost impossible to make the necessary local manipulations. Of the forty successful cases, all presented well-marked diphtheritic symptoms. The treatment consisted in the energetic application of the petroleum every two hours by means of a brush, with the addition, in some cases, of sprays of carbolised water. As a result a rapid softening and shedding of the false membranes followed. In most cases the membrane reformed, but was less thick and extensive, appearing in patches, between which healthy mucous membrane appeared, finally encroaching on the patches, and permanently taking their place when the latter gave way a second time to the application. In seven of the cases there was paralysis of the soft palate. The petroleum was not found as disagreeable as might be imagined, for it was only towards the termination of the treatment that the patients began to complain of any unpleasant taste. M. Larcher concludes from the foregoing that if the future gives an analogous proportion of successful results by this method, it may be submitted with safety that—(1) Petroleum may be considered capable of curing diphtheria; (2) that its employment is unattended by any serious inconvenience; (3) that its use does not preclude other applications; (4) that the duration of the treatment varies between eight and eighteen days; and (5) that—a point of no small importance—in connexion with these forty-two cases, in no instance was there any spread of the contagion, a result not always achieved with other methods of treatment.

Paris, March 15th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Investigation of Quarantines by Congress.

THE introduction of typhus fever into this country through the port of New York has become sufficiently serious to excite the attention of Congress. The immigrants of Russian Hebrew extraction who were carriers of the pestilence have dispersed throughout the country, and new cases of typhus fever are daily reported from widely different localities. Much blame is attached to the quarantine officers at this port for allowing these immigrants to

Digitized by Google

disembark, and finally a joint resolution has been introduced into Congress directing a committee to investigate the charges made against the management of the quarantine. Probably the explanation of this misadventure will be found in the recent change of quarantine officials by the State government. The office of health officer of this port is a local political prize which is eagerly sought on every change of the political complexion of the State. If the coming investigation should result in placing the quarantines of the country under the government at Washington, with such regulations as would give permanency to their administration, the change would be in the interests of both commerce and the public health.

Typhus Fever in New York.

The typhus fever introduced by Russian Jews into this city has not gained any foothold apparently, owing to the energetic efforts of the health authorities to isolate the first cases. It is true that new cases almost daily occur in the crowded tenements, but each one is immediately removed to the hospital, thorough cleansing and disinfection secured, and thereafter a close watch is kept upon the place As yet all of the cases are limited to the immigrants. Cases of typhus fever are still reported from distant parts of the country, but they are confined to the immigrants of the ill-fated ship from Marseilles.

A Laboratory of Hygiene.

Through the generosity of a citizen the University of Pennsylvania has been able to build and equip a Laboratory of Hygiene. The formal opening of the institution took place on Feb. 22nd. The building is arranged throughout for scientific research and instruction, and each department is adapted and equipped for its special kind of investigation. This is the first Laboratory of Hygiene established in this country, and gives promise of being very successful. The director of the Institution is Dr. John S. Billings, of the U.S. Army.

Asylums for the Chronic Insane.

The proper classification of the insane in State care into the acute and chronic gave rise to the erection of an asylum (Willand) in the State of New York for the chronic insane. This asylum proved a great success. The asylums for the acute insane were relieved of the pressure upon their space by the chronic cases, and the chronic insane received that kind of care and treatment which they specially need. Within the last year this State has, however, abandoned its former policy and converted its asylum for the chronic insane into a mixed asylum. Meantime, the States of Massachusetts and Pennsylvania have adopted the policy of separating their chronic from the acute insane, and establishing separate asylums for each class. It is believed that New York has taken a backward step.

New York, Feb. 27th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

The Pahiatua Poisoning Case.

BOXING DAY will long be remembered in the Masterton district, for a most alarming and extraordinary occurrence took place on that day. It appears that on Christmas Day last a wedding party assembled at the house of Mr. Naylor of Pahiatua, and the usual wedding breakfast was partaken of. In all, the party numbered about thirty. After the festivities were over the party dispersed, but a number again sat down on the following day (Boxing Day) as guests of Mr. Naylor. Practically the same food was partaken of, with the exception of a dish of sliced lamb. However, early on the morning of Dec. 27th the whole of the guests of the 26th (about twenty in all) were attacked with intense vomiting, diarrhœa, abdominal pain, and violent cramps. These symptoms developed for the first time twelve hours after the repast. There being no medical man immediately to hand, the local chemist was sent for, and he expressed the opinion that the symptoms were those of influenza coupled with biliousness resulting from the feasting of the previous day, and he prescribed according to his lights. Mr. Milne of Woodville, however, was then secured, and he was called in to attend the victims. He deposed at the inquest that he concluded from what he was told that the patients were suffering from an irritant poison, and that he was satisfied with the treatment adopted by the chemist, and ordered its continuance. At the same time he admitted that he had not ascertained what that treatment was, but assumed what it had been from the medicine he saw there. Being asked why he did not communicate with the police as to the fact that his patients were suffering from poison, Mr. Milne replied, "I suppose it must be put down to my ignorance or want of knowledge of the matter, and the fact that I did not think the cases sufficiently serious." It is to be regretted that he omitted to give instructions to keep some of the vomited matter. The symptoms of the victims increasing, Mr. Davenport of Woodville was sent for, and, diagnosing the cases as those of poisoning by an irritant, he administered emetics, which gave almost immediate relief to several of the guests; but on the following day most alarming symptoms developed, and Mr Hosking was communicated with. He first saw Mrs. Peter Dickson and found her in a serious condition, convulsions having set in. Having done everything in his power to afford relief, he was hurried to the bedside of Mr. Dickson, whom he found in an unconscious state, and suffering from tetanic convulsions. Mr. Dickson died shortly after the doctor's arrival. Mr. Joseph Moore of Rockroad had died under exactly similar conditions half an hour previously. Although all the guests suffered more or less, fortunately these are the only deaths to record. So many different foods were partaken of at the dinner that it was not easy to trace the direct source of the disaster. It was reported at the time that the calamity was the result of a practical joke, some person having mixed oxalic acid with the food, thinking it was Epsom salts. Arsenical poisoning was the other theory propounded. It was supposed to have been placed in the food by a disappointed lover. The late Mr. Dickson was an old settler in the colony, and was much respected. He was the proprietor of a large drapery business, and was a prominent member of the Masonic order. The inquest has just concluded. The Government analyst stated that the analysis of the stomach and other organs led to the conclusion that the victims had died from the effects of arsenical poisoning, but that no evidence of poison could be discovered in the articles of food taken from Mr. Naylor's house. Mrs. Naylor stated that some of the roast lamb had been cut up in slices late on Christmas Eve, but was not eaten by anyone except Mr. Naylor, who took a few slices for his supper about 11 o'clock. The witness, returning home from her daughter's house early on Boxing Day morning, noticed the scullery door open, and saw a man going in the direction of the main road. She shouted out to this person, but received no reply. On going into the scullery after this incident she found the cloth over the lamb had been disturbed. The witness stated that the lamb which remained over after the Boxing Day repast was given to a cat and a dog, and that the animals became very ill shortly after eating it. The engagement between her daughter and Mr. Sedcole had existed for five years, and she was not aware of any other lover in the case. She was not aware that she had any enemies, but she knew that some of the guests had been threatened. The result of the inquest shows nothing to connect the two facts elicited—firstly, that the poison was arsenic; and secondly, that there had been bad feeling between some of the parties; and it is still left to discover who put the arsenic in the lamb. An open verdict was the result.

New Zealand.

Obituary.

GEORGE SHEARER, M.D., L.R.C.S.

WE regret to announce the death of Dr. George Shearer, of Upper Parliament-street, Liverpool. He had attended a funeral, and on his return complained of having caught a chill. His complaint soon developed into acute pneumonia, to which, despite unremitting attention, he at last succumbed. He was a gentleman of varied talents. Born at Thurso and educated at Edinburgh University, where he graduated in 1859, his career was throughout distinguished and successful. He was gold medalist in anatomy, chemistry, surgery, and materia medica, and took Sir James Simpson's silver medal in midwifery. He was an F.L.S. and lecturer on botany in the medical faculty

Digitized by Google

at the Liverpool University College, senior assistant physician to the Consumption Hospital, and lecturer on animal physiology and general biology in the School of Science. One of his first appointments was that of resident physician at Edinburgh Royal Infirmary, after leaving which he spent some years as voluntary missionary in China. Settling in Liverpool, he commenced practice about eighteen years since, and endeared himself to a very wide circle. He was the author of several works, of which the following were the most important: "The Neurosis of Sensibility," which he composed for the "Star" thesis; the "Autobiography of an Atom of Carbon;" and in 1881 an "Essay on the Best Means of Curing the Opium Habit," which carried off a £50 prize. His obliging disposition and engaging manner, together with his ability, enabled him to make friends of all his professional brethren.

BEN. TYDD HEUSTON, L.R.C.P. & S. EDIN.,
WESTERN AUSTRALIA.

INFORMATION has just been received by his friends in this country of the death of Mr. Ben. Tydd Heuston, surgeon in the Colonial Medical Service, and resident magistrate of the district of Derby in Western Australia. The name will recall to many of his old classmates the bright face and jovial manner of their erstwhile companion, who has been cut off in the pride of manhood at the early age of forty-two. A native of Ireland, he received his medical education in Edinburgh. After practising for some years in Dunse, in the south of Scotland, he joined the Colonial Medical Service, and for fourteen years was stationed in the Falkland Islands. Thereafter he was transferred to the south of Western Australia, and held appointments at Bussleton, Pinjarrah, and Derby. On his arrival in Western Australia his abilities were soon recognised by the Premier, and he was appointed resident magistrate, first in Pinjarrah, near Perth, and afterwards promoted to Derby. He was highly esteemed by the whole community, to whom his sudden death from apoplexy came as a great shock. Much sympathy has been expressed by all, from the Premier downwards, for his widow and family of four young children. His loss will be very much felt in the district.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation held last week the following degree was conferred:—

Doctor of Medicine.—Walter J. Turrell, Turrell's Hall.

UNIVERSITY OF CAMBRIDGE.—A synopsis of the regulations for the examination in Sanitary Science of the University has just been issued. Two examinations in so much of State Medicine as is comprised in the functions of medical officers of health will be held during the year 1892 in Cambridge, beginning on the first Tuesday in April and in October respectively, and ending on the following Friday, or at latest on the following Saturday. With certain provisions, any person whose name is on the Medical Register of the United Kingdom may present himself for this examination. The names of candidates, with the necessary certificates, should be sent to the registrar, W. Clark, Esq., on or before March 29th.—At a congregation held last week Dr. Corfield (Oxford), Dr. A. Ransome (Gonville and Caius), Dr. J. L. Notter (Dublin), and Dr. Thorne Thorne (London) were appointed examiners in State Medicine. At the same meeting the following degrees were conferred:—

Doctors of Medicine.—Gerald Crowfoot Fitzgerald, Gonville and Caius; Arnold Clarkson Ingle, non-collegiate.

Bachelors of Medicine and Bachelors of Surgery.—Herbert Edward Durham, King's; Joseph George Hulbert and Frederick Meadows Turner, Trinity; Edward Hugh Edwards Stack, Pembroke; Maurice Craig and Thomas Wilfred Scott, Gonville and Caius; Joseph Beckett Gillam and Sidney Herbert Lee, Downing.

The examinations for Medical and Surgical Degrees in the Easter term will commence on the following dates:—Third Examination for M.B. degree, Parts I. and II., Tuesday, April 26th; Master of Surgery, Friday, April 29th. Second Examination for M.B., Part I., Monday, June 13th; Part II., Tuesday, June 7th. First Examination for M.B., Part I., Tuesday, June 7th; Part II., Thursday, June 9th.

ROYAL INSTITUTION.—Dr. B. Arthur Whitelegge will, on Thursday next (March 24th), begin a course of three lectures on "Epidemic Waves."

FOOTBALL CASUALTY.—Whilst playing in a game last week in the Pinderfields-road Recreation Ground, Wakefield, a young man aged twenty fractured his leg.

CITY OF LONDON AND EAST LONDON DISPENSARY.—The annual report for 1891, read at the meeting of the governors on the 16th inst., Earl Manvers in the chair, states that 37,352 patients were treated during the year, of whom 1716 were free, the renewals being 26,553. The cash statement shows a balance in hand of £357 4*s.* 11*d.*

BURNING OF A LUNATIC ASYLUM AT JACKSON, MISS.—The four-storey main building of the State Asylum for the Insane was set on fire on Feb. 10th by an inmate of the institution. There were 600 inmates in the building, most of whom were asleep when the flames were discovered. Through the exertions of the superintendent, Dr. Mitchell and his subordinates all were saved and safely transferred to the wings disconnected from the burning pile.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD.—For nearly eighty years the benefits of this charity have been bestowed in the midst of densely populated districts of the metropolis, and the work is daily increasing. The new wing now completed, while increasing the usefulness of the hospital, will necessarily add to the cost of maintenance. The report for the past year read at the meeting of the court of governors on the 14th inst. states that the reliable income is quite insufficient to meet the expenditure.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—This institution, which has carried on its benevolent work for upwards of twenty-two years, maintains its sphere of usefulness; 722 in-patients were treated during the past year, making a total number of 11,029 since the hospital was established. The year's income, including £1104 from legacies, was £10,103 18*s.* 11*d.*, while the expenditure amounted to £10,941 7*s.*, the increase being largely owing to heating and ventilating improvements. Her Majesty the Queen has become an annual subscriber of £10.

YORK COUNTY HOSPITAL.—The Dean of York presided at the annual meeting of the governors held on the 8th inst. The in-patients treated in 1891 were more by sixty-six than the previous year. The training school for nurses continues to make satisfactory progress. The year's fees amounted to £212 5*s.*; the net income, exclusive of legacies, was adequate to provide for the expenditure; the annual subscriptions, which rose at a bound as the result of special efforts two years ago, had been sustained. From legacies the receipts exhibit a total of £1968. Plans for certain improvements, involving an estimated cost of £4314, were approved.

THE GENERAL INFIRMARY, LEEDS.—The annual report for 1891 just issued shows a large addition to the number of in- and out-patients treated at the infirmary and the Ida Hospital. The horse ambulance continued to be of great service, and was called into requisition on 498 occasions. The treasurer's revenue account showed that the receipts were £20,154 12*s.* 6*d.*, while the total expenditure for maintenance in the infirmary and the Ida Hospital was £20,894. The new buildings of the infirmary are rapidly approaching completion, and will be ready for occupation in a few months. The maintenance of the new hospital, it is estimated, will cost at least £5000 per annum more than the present establishment.

VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.—The annual report for the past year states that since the establishment of the pension fund for all nurses in the employment of the hospital eleven nurses have joined the fund; that 885 children had been treated in the wards of the hospital; 196 were sent to the convalescent branch at Margate, and there were 44,408 attendances in the out-patients' department. Anæsthetics were given on 972 occasions, for operations and medical examinations. The home at Broadstairs will be ready for the reception of patients early in April, but a further sum of £1500 is still required to enable it to be opened free from debt. The reduction of the charge of endowing a cot in the hospital from £1000 to £500 has been agreed to.

DR. MACPHERSON LAWRIE, J.P. Dorset, has been elected a member of the Dorsetshire County Council.

SUPERANNUATION GRANT. — Mr. G. H. Davis, L.R.C.P. Edin., M.R.C.S., lately medical officer of the fourth district of the Bradfield Union, has been granted a superannuation allowance of £27 17*s.* per annum.

PRESENTATION.—Mr. J. M'N. O'Keeffe, L.R.C.P., L.R.C.S. Edin., was presented on Monday with an illuminated address and a cheque by a large number of his fellow townsmen, in recognition of the valuable public services he had rendered to the borough.

ANOTHER CENTENARIAN.—A correspondent telegraphs: "'Granny' Morphew, the well-known centenarian of Ham, Surrey, died to-day (Tuesday) at the age of 106. She had lived at Ham nearly all her life, had been confined to her bed for a comparatively short time, and retained her mental faculties to the last."

BRITISH INSTITUTE OF PREVENTIVE MEDICINE.—The following donations, among others, have already been promised:—His Grace the Duke of Westminster, £1000; Ludwig Mond, Esq., £2000; Sir Joseph Lister, Bart., £300; Sir William Roberts, F.R.S., £300; Sir Henry Roscoe, £100; Dr. M. Armand Ruffer, £100; the Right Hon. the Earl of Derby, £1000; His Grace the Duke of Devonshire, £1000; Dr. P. H. Pye-Smith, £105.

A NEW MEDICAL SOCIETY.—A Society having the name of the Bolton and District Medical Society has been formed in Bolton. The following are the list of office-bearers. President: F. B. Mallett, M.D., J.P. Vice-Presidents: James Robinson, M.D., and Mr. J. Johnson Martin. Hon. Secretary: Nathan Raw, M.D. Hon. Treasurer: Peter Yates, M.D. Hon. Librarian and Editor: J. Hilton Thompson, M.D. Committee: Mr. E. M. Garstang, J. Johnston, M.D., Mr. A. Kershaw, Mr. H. Murphy, J. E. Panton, M.D., and Mr. G. Patrick.

WARNEFORD HOSPITAL, LEAMINGTON. — Lord Leigh occupied the chair at the annual meeting held last week. The annual report, the fifty-seventh, stated that the erection of the new wing would cost altogether upwards of £14,000. This would exhaust the resources at the disposal of the committee for building purposes, and to carry out the whole proposed scheme additional funds were required. The financial statement was read by the secretary, and in moving the adoption of the report, which was carried, his lordship advocated a registration fee, the provision of a ward for paying patients, and that all patients should be allowed tea and sugar free.

THE St. Mary's Hospital Athletic Club's dinner was held on Tuesday last at the Holborn Restaurant. The dean of the medical school, Mr. George P. Field, presided, supported by about 150 of the staff and students. Messrs. Moon and Wall responded for football, Mr. Poynton for cricket, Mr. G. Mould for athletics, and Captain A. Thorne for the shooting club. The toast of the staff was proposed by Mr. H. E. Lawrence and responded to by Dr. Maguire. Dr. Sidney Phillips proposed the chairman, who congratulated the association football team in playing a drawn game (one goal all) with St. Bartholomew's in the final tie. The chairman also announced that he had just heard from Dr. Broadbent that the Prince and Princess of Wales were coming in October next to lay the foundation stone of the new buildings in Praed-street, and that their Royal Highnesses had consented to call the new portion of the hospital "The Clarence Memorial Wing," in memory of the late Duke of Clarence. The governors had already spent £45,000 in buying the land and houses. About 100 beds would be added to the hospital, and there would also be provided a nurses' home, special wards and lying-in wards, a new out-patient department, and also a presidential college in the hospital grounds. His Royal Highness Prince George of Wales had also that day consented to be president of the hospital.

MEDICAL NOTES IN PARLIAMENT.

Metropolitan Hospitals Committee.

IN the House of Lords on Tuesday, March 15th, the Earl of Kimberley, in the absence of Lord Sandhurst, moved that a Select Committee be appointed to consider the evidence taken during the sessions of 1890 and 1891 with regard to all hospitals and provident and other public dispensaries and charitable institutions within the metropolitan area &c., and to report thereon to the House; and that the following lords be named of the committee: The Archbishop of Canterbury, Earl Cadogan, the Earl of Winchilsea, the Earl of Lauderdale, Earl Spencer, Earl Cathcart, the Earl of Kimberley, Lord Zouche, Lord Saye and Sele, Lord Clifford of Chudleigh, Lord Sandhurst, Lord Fermanagh, Lord Lamington, Lord Sudeley, Lord Monkswell, and Lord Thring.—The motion was agreed to.

Registration of Midwives.

In the House of Commons, on Thursday, the 10th inst., Mr. Balfour, in reply to Mr. Pease, said the Government had no objection to the appointment of a Select Committee to inquire into the question of the registration of midwives.

Surgery Professorship at Netley.

Sir W. Foster asked the Secretary of State for War whether it was the intention of the authorities to second Brigade-Surgeon-Lieutenant-Colonel Godwin, about to be promoted as Surgeon-Colonel, while holding the appointment of Professor of Military Surgery at the Royal Victoria Hospital, Netley.—Mr. E. Stanhope: The officer in question is not seconded in his rank, but is made supernumerary to the medical staff. His appointment to a professorship therefore causes no reduction in the number of medical officers.

The Metropolitan Water-supply.

The names of the Commissioners appointed on the Royal Commission to consider the question of the Metropolitan Water-supply are—Lord Balfour of Burleigh (chairman), Sir George Barclay Bruce, C.E., Professor James Dewar, F.R.S., Sir Archibald Geikie, Mr. George Henry Hill, C.E., Mr. James Mansergh, C.E., and Dr. William Ogle, F.R.C.P.—The reference which the Commission has to consider is "Whether, taking into consideration the growth of the population of the metropolis, and the districts within the limits of the metropolitan water companies, and also the needs of the localities not supplied by any metropolitan company, but within the watersheds of the Thames and the Lea, the present sources of supply of these companies are adequate in quantity and quality, and, if inadequate, whether such supply as may be required can be obtained within the watersheds referred to, having due regard to the claims of the districts outside the metropolis, but within those watersheds, or will have to be obtained outside the watersheds of the Thames and the Lea."

Police and Sanitary Regulations Bills.

On Thursday, the 17th, in the House of Commons a number of instructions were adopted for the use of the Select Committee on Police and Sanitary Regulations Bills. One was to the effect that the Committee shall not sanction in any Bill referred to them any clauses relating to matters which are the subject of provisions in "The Infectious Disease Notification Act, 1889," "The Public Health Acts Amendment Act, 1890," "The Infectious Disease (Prevention) Act, 1890," or "The Museums and Gymnasiums Act, 1891," unless the Committee report that the insertion of such clauses ought to be allowed, with the reasons on which their opinion is founded. Dr. Farquharson, while not objecting to this instruction, emphasised the need for the Committee having a wide discretionary power, and reminded the House that many important provisions in our health legislation had been initiated in private Bills which had passed the scrutiny of this Committee. The President of the Local Government Board assured the hon. member that there was no desire on the part of the Government to interfere with the good work done by this Committee.

The Opium Trade.

Colonel Hughes presented a petition signed by 17,965 inhabitants of India against the growth of the poppy and the common sale of opium.

A Dangerous Practice.

Colonel Malcolm put a question to the President of the Board of Agriculture with reference to the practice of throwing over carcases from cattle ships in the immediate proximity of our coasts. Mr. Chaplin, in the course of his reply, said that any person who threw the carcase of an animal which died from disease, or was slaughtered in consequence of disease, into the sea within three miles of the shore was liable to a penalty. In the event of his becoming aware of the commission of such an offence he would at once take steps for proceedings against the offender. It was obvious, however, that the offence was one difficult to discover.

METROPOLITAN ASYLUMS BOARD.

Return of Patients remaining in the several Fever Hospitals of the Board at Midnight on March 15th, 1892.

Medical Diary for the ensuing Week.

Monday, March 21.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.
ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.
ROYAL COLLEGE OF SURGEONS.—4 P.M. Professor Charles Stewart: The Physiological Series of Comparative Anatomy in the College Museum.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Mr. T. P. Pick: Injury to Median Nerve; Operation; Restoration of Function. Dr. M. Murray: Multiple Sarcomatous Tumours.—Mr. E. Owen: Infant after Acute Epiphysitis.—Dr. T. C. Fox: Three cases of Senile Tuberculosis of the Skin.—Mr. C. B. Lockwood: Case of Nephrectomy.—Mr. W. H. Battle: (1) Compound, Comminuted, Depressed Fracture of the Skull treated by Trephining and Replacement of Bone; (2) Result of Partial Removal of the Clavicle for Necrosis.—Mr. Sheild: Spina Bifida Occulta; Necrosis of Foot and Talipes.

Tuesday, March 22.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.
GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Professor V. Horsley: The Brain.
ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Victoria Embankment).—5 P.M. Dr. Sidney Martin: Chemical Pathology of Diphtheria compared with that of Anthrax, Infective Endocarditis, and Tetanus. (First Goulstonian Lecture.)
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Mr. Richard Barwell: The Operative Treatment of Congenital Dislocation of the Hip.—Mr. Rickman John Godlee: A case of Ligature of the Second Part of the Left Subclavian Artery for the Cure of an Axillary Aneurysm.

Wednesday, March 23.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.
CHARING-CROSS HOSTITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.
ROYAL COLLEGE OF SURGEONS.—4 P.M. Professor Charles Stewart: The Physiological Series of Comparative Anatomy in the College Museum.
HUNTERIAN SOCIETY.—8.30 P.M. Mr. A. H. Tubby: The Treatment of Compression Paraplegia following Pott's Disease.—Dr. F. J. Smith: On Three cases of Intestinal Obstruction.

Thursday, March 24.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.
ROYAL INSTITUTION.—3 P.M. Dr. B. A. Whitelegge: Epidemic Waves.
ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Victoria Embankment).—5 P.M. Dr. Sidney Martin: Chemical Pathology of Diphtheria compared with that of Anthrax, Infective Endocarditis, and Tetanus. (Second Goulstonian Lecture.)

ROYAL INSTITUTION.—9 P.M. Mr. John Evans: Posy Rings.

Saturday, March 26.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.
ROYAL INSTITUTION.—3 P.M. Prof. J. F. Bridge: Dramatic Music.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

TO OUR READERS.

INSET ADVERTISEMENTS.

OUR attention has been called by a correspondent, to whom we offer our best thanks, to a practice most reprehensible, as we venture to think, but which, though it appears to affect us in a measure, we have no power whatever to control. We refer to the introduction into copies of THE LANCET of fly-sheet advertisements inserted between the pages of the journal. Advertisements which have been refused admission to our pages are sometimes thus surreptitiously inserted when the issue has passed out of our hands into those of the newsvendor. We trust that our readers will for the most part see through this transparent artifice, and be so far from giving credit to an advertisement on any such ground as rather to regard it as a suspicious circumstance that the connexion of the advertisement with THE LANCET should be of so adventitious a kind. Such advertisements as we think it right to publish do not appear in the leaflet form, and although we cannot, as we have said, control the action of the newsvendors, we can at least denounce the practice, and invite our readers to withdraw their custom unhesitatingly and at once from any tradesman who adopts it.

SMALL BUT IMPORTANT DETAILS.

To the Editors of THE LANCET.

SIRS,—In his excellent and practical paper on Piles at the Medical Society Dr. Lauder Brunton calls attention to the dangers of the ordinary w.c., not only in this but in other more serious illnesses. The window of the closet is usually kept open in all weathers, and frequently there is a strong up-draught of intensely cold air from the pan. During the late epidemic I have known many lives endangered by a visit to a cold and draughty w.c. when the patient has been in a profuse perspiration and suffering from pneumonia after influenza. A few simple remedial precautions are within the reach of all; first, let the window be always shut at night, and if possible a small jet of gas left burning, or a small paraffin lamp be placed on the floor; secondly, a can of hot water should be poured into the closet pan just before its use. If the air be damp and cold, the temperature of so small a chamber may be easily raised *pro tem.* by very carefully lighting and flaring a piece of newspaper in it, or by keeping in the closet a large can of boiling water, which may be renewed every few hours. These may, to some, appear absurdly trivial details, but on such apparent trifles a life may, and often does, depend. I am, Sirs, faithfully yours,

Folkestone, March 14th, 1892. C. EGERTON FITZGERALD, M.D.

MEASUREMENT OF SCHOOL CHILDREN.

A PROPOSITION has been forwarded to Mr. Shaw, the Chairman of the Rochdale School Board, from Archdeacon Wilson, proposing that some measurement of the height and weight of boys at the elementary schools should be made every five or six years, to show whether the population is improving or deteriorating physically. Archdeacon Wilson maintains that physical training is recognised as a part of elementary education, and that measurements are the only efficient results of such calisthenics, drill, or gymnastics as may be introduced into the schools which can be relied on.

Mr. Wagstaff.—The information will be found under various headings in the First Report of the Royal Commission on Vaccination, issued on Aug. 12th, 1889, and notably in the Tables supplied by Dr. William Ogle, which are contained in Appendix II., page 114.

"A CAUTION."

To the Editors of THE LANCET.

SIRS,—It having come to my knowledge that some person is writing letters to old London Hospital men, stating that the writer, Francis Joseph Pound, is in London, in bad health and desperate pecuniary circumstances, and, of course, requiring pecuniary assistance, may I ask you to be good enough to allow me to contradict this begging-letter impostor's statements, as my brother, Mr. Francis Joseph Pound, M.R.C.S.Eng. &c., is still in Fiji in the Colonial Medical Service, and in no way requiring assistance?

I am, Sirs, yours faithfully,

Cdiham, March 16th, 1892. CLEMENT POUND, L.R.C.P.Lond.

MEDICAL ETHICS AND THE LAY PRESS.

Mr. John Weller writes to us to say with regard to the paragraphs quoted by us last week from Essex papers that he "had nothing whatever to do with them, either directly or indirectly, in any shape or form." Of this we are quite sure, and gladly accept our correspondent's disclaimer. At the same time we must always hold that the insertion of such paragraphs in the lay press cannot too strongly be deprecated.

Dr. Lys will perceive that the question has entered upon a phase which renders unnecessary correspondence on the point to which he refers.

THE CARPENTER AND DUKES FUND.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to acknowledge in THE LANCET the receipt of the follo wing additional subscriptions to the above fund?

I am, Sirs, yours faithfully,

50, George-street, Croydon, March 14th, 1892. WM. F. COLES.

Dr. E. E. Shaw	..	£2	2	0	Dr. C. Holman	.. £1	1 0
Dr. W. M. Ord	..	1	1	0	Drs. Hearnden and Atkins	2	2 0
Mr. E. Marshall	..	1	1	0			

CHAPPED HANDS.

Penton writes to us to say that he has under his care a case of chapped hands which seems to defy all his efforts. They will heal for a few days; but then cracks appear, and soon deepen into bleeding cuts. Can anyone suggest a mode of treatment for such a case? Glycerine and unguents of various kinds have been tried.

Waterloo.—We must refer our correspondent to the Students' Number of THE LANCET published on Sept. 6th last.

Dr. Joseph McFarland (Philadelphia).—We must refer our correspondent to the author of the lectures.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In your report of the meeting of the London Obstetrical Society there is a very serious error. I am reported to have said: "If the labour had not set in it should be induced." Now, I have always urged that *the operation should only be performed after labour has set in*, and when the os uteri is partially dilated. I have five cases coming during March and April, and in each case I shall operate during labour.

I am, Sirs, yours faithfully,

Glasgow, March 15th, 1892. M. CAMERON.

THE IDEAL NUTRITIVE BEVERAGE,
ESSENTIA MALTI (KEPLER).

WE have recently introduced a new food agent and aid to the digestion of farinaceous substances under the above name. This preparation is manufactured by a modification of the KEPLER process for making the well-known **Kepler Extract of Malt.**

The KEPLER ESSENCE OF MALT contains a large amount of **Diastase** and natural mineral phosphates, and a considerable amount of tissue-forming substances. *The immense superiority of this preparation over ale and stout* is at once apparent when the process of manufacture is considered in detail. In making ale and stout the carbo-hydrates (so valuable as nutrient material) and the diastase (a most important principle of Malt, being of special service in errors of nutrition accompanied by digestive derangement) are sacrificed for the production of alcohol; whereas *in the KEPLER ESSENCE OF MALT these are carefully preserved intact.* This Essence is therefore an ideal aid to digestion and nutrient agent. **A wine-glassful of the Kepler Essence of Malt contains more elements of nutrition than a pint of the finest alimental stout.**

The flavour of the ESSENCE OF MALT is delicious. It is admirable as a table beverage when diluted with aerated water, and as an addition to milk for infant and invalid dieting; for it sweetens it and facilitates its prompt and perfect digestion. The Essence may be taken in coffee, gruel, aërated or plain water, wine, or mixed with any farinaceous pudding. As an addition to the food for young children its value cannot be over-estimated. It increases the value of all farinaceous food, and prevents the starch in farinaceous food and large clots of curd in milk diet overtaxing the power of the digestive functions.

For Lactating Women the ESSENCE OF MALT (KEPLER) contains many desirable properties; it quickly increases the flow and enriches the quality of the milk. It is serviceable as a laxative for young children, especially when constipation depends upon the defective digestion of starch. As a food beverage, it cannot fail to be productive of the highest benefit, either in **acute disease** or during **convalescence**; in fact, wherever there is defective nutrition, the KEPLER ESSENCE OF MALT is useful as a nutritive food.

As a Linctus, the Essence of Malt food, swallowed slowly, in the troublesome, dry, laryngeal cough, and the hacking cough of puberty or consumption, is pleasantly grateful and soothing, aids digestion, and builds up the tissues.

The KEPLER ESSENCE OF MALT is supplied to the profession in champagne pints at 1s. 2d. each.

Goulstonian Lectures

ON THE

CHEMICAL PATHOLOGY OF DIPHTHERIA COMPARED WITH THAT OF ANTHRAX, INFECTIVE ENDOCARDITIS, AND TETANUS.

By SIDNEY MARTIN, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION, BROMPTON; LATE PATHOLOGIST TO THE MIDDLESEX HOSPITAL.

LECTURE I.

INTRODUCTION.

MR. PRESIDENT,—I must in the first place express my sense of the honour which has been conferred upon me by my appointment as Goulstonian Lecturer, and I trust that what I shall bring forward will be deemed worthy of the traditions of this distinguished College. The subject I have chosen is the Chemical Pathology of Diphtheria compared with that of Anthrax, Infective Endocarditis, and Tetanus—that is, of two diseases, anthrax and infective endocarditis, eminently febrile, and of two, diphtheria and tetanus, with symptoms specially referable to the nervous system. They are all disorders in which the symptoms are due to a primary infective agent or living contagium. A mere study of the morphology of this primary infective agent does not explain the symptoms of the diseases; still less is this so when we consider that in diphtheria and acute traumatic tetanus the infective agent has been found only at the point of inoculation of the disease, and does not diffuse itself throughout the body. Beside the morphological characters of the infective agent and a histological examination, a chemical investigation is necessary; and to this we shall probably in the future have to look not only for an explanation of the symptoms of infective disorders, but for a scientifically grounded method of treatment. The direction of the research which I shall bring before you is the investigation in these specific disorders of the presence of specific poisons, the product of the primary infective agent. I will, as an explanatory introduction, state quite briefly what I have already published on the chemical pathology of anthrax—a disease which serves as an excellent example, since its microscopical anatomy and bacteriology have been very completely worked out. It is characterised in its anatomy by the presence of the bacillus anthracis at the seat of inoculation and in different organs of the body, especially the spleen; and in symptoms by the onset of fever, by the presence of great prostration, and by the occurrence of stupor ending in coma and death.

ANTHRAX.

If the bacillus anthracis is grown in a medium which resembles the fluids of the body in containing an animal proteid and a certain proportion of mineral salts, it digests the proteid with the formation of products resembling chemically those found in peptic and in tryptic digestion, with the exception, however, that the final product is a base, an organic body forming salts with acids.

Primary agent or primary infective agent.	Ferment.	Digestive products.
Living cell	Pepsin	Syntonin, hetero-albumose, proto-albumose, deutero-albumose, peptone.
Living cell	Trypsin	Globulin-like body, tryptone (peptone), leucin, tyrosin, a bitter body.
Bacillus anthracis	(Anthrax digestion)	Hetero-albumose, proto-albumose, deutero-albumose, peptone, leucin, tyrosin, alkaloid (base).

A glance at this table will show you the relation between anthrax digestion and those by trypsin and pepsin. It is similar to the peptic digestion of proteids in the formation of albumoses and peptone, and it is like tryptic digestion in the fact that the proteid molecule is split up into non-proteid organic bodies, the chief of which is the anthrax base. The two chief proteid digestive products which concern us at present are proto-albumose and deutero-albumose. They have, in common with peptone, the following reactions:—(1) They are soluble in water, cold or boiling, forming a yellow solution; (2) they give a pink colour (biuret reaction) with copper sulphate and potash solution; (3) they are precipitated by alcohol, but not coagulated by it. In these reactions they differ from hetero-albumose and ordinary globulins and albumens. They are distinguished from each other by the following reactions:—Proto-albumose is precipitated in the cold by nitric acid, the precipitate being soluble on heating, reappearing on cooling, &c.; it is also precipitated by saturation with sodium chloride. Deutero-albumose is not precipitated by nitric acid, unless a certain percentage of sodium chloride be added, and is not precipitated by saturation with this salt if the liquid be only slightly acid. Peptone is not precipitated by nitric acid, and therefore the mode of precipitation by this reagent is a distinguishing reaction between the two chief albumoses and peptone. The anthrax albumoses have the same chemical characteristics as those formed in peptic digestion. The anthrax alkaloid is an amorphous yellow body with an alkaline reaction, soluble in alcohol and in amyl alcohol, and precipitated by many reagents which throw down alkaloids, but not by Mayer's solution.

Chemical products of tissues of anthrax animals.—The results of the investigation of the artificial chemical products of the bacillus anthracis indicated the chemical bodies to look for in the blood and other tissues of animals suffering from the disease. In guinea-pigs and a sheep, which were inoculated with anthrax and died from it, it was found that both classes of products were present in the œdema produced at the site of inoculation, in the blood, and in the spleen; and in a man who died of anthrax in Guy's Hospital from the natural disease the same results were obtained; and in this case it was also found that both classes of products were excreted in the urine. An approximate estimation of the amount of anthrax products present in the body at death is seen in the following table, in which the amount in the local lesion, the spleen, and the blood is shown.

In Full-grown Sheep dead of Anthrax.

	Albumoses.	Alkaloid.
From local lesion	0·167 grm.	0·1346 grm.
From spleen	0·191 ,,	1·2080 ,,
From blood (chiefly deutero-albumose)	0·455 ,,	0·6430 ,,
Total	0·813 grm.	1·9856 grm.

It will thus be seen that in the natural disease the two classes of products are both present, but that the amount of the alkaloid is much greater than that of the albumoses, and the results of the investigation of the physiological action of the products show that the alkaloid is the chief agent in producing death. In mice so small a quantity of the mixed products as 18 milligrammes of the albumoses and 28 milligrammes of the alkaloid will produce death in nineteen hours. In guinea-pigs in which the mixed products are injected subcutaneously there is at first fever, which may pass off. If a large dose of the alkaloid is given in proportion to the albumoses, coma ensues, which may last as long as fifty hours; and at the same time there is a spreading œdema at the seat of inoculation. During this coma there is no high fever, and there may actually be a depression of temperature. The *rôle* which these products individually play is seen by injecting them separately into animals. The albumoses are the fever producers; the alkaloid is the coma producer.

This chart shows the fever produced in guinea-pigs by a subcutaneous inoculation of anthrax albumoses compared with that produced by peptic albumoses; the dose in all is the same—namely, 0·2 gramme per kilogramme of body weight. The upper line shows a rise of temperature two hours after inoculation, and lasting over twenty-four hours; this is of anthrax albumoses unheated. The second thin line shows the fever produced after boiling for thirty seconds; it is slightly less than the first. The third dotted line shows the fever produced by peptic albumoses, which is not so well marked as that of the unheated anthrax albumoses. These animals showed no other symptoms but fever. The prolonged effect of the anthrax albumoses is best seen when they are injected directly into the circulation. The effect of the injection of a dose of 0·122 gramme per kilogramme of body weight into the marginal vein of the ear of a rabbit is a rise of temperature of over 40 in

four hours after inoculation, and a continuance of the fever during the second and third day of experiment, the temperature being normal on the fourth day. Three times this dose produces a very moderate rise of temperature and then a fall, ending in death in a few hours. The alkaloid produces either no rise of temperature or a very slight one; it is a local irritant, producing œdema, and is the cause of the coma. The investigation of the chemical pathology of anthrax gives us, therefore, a clear idea as to the means by which the bacillus anthracis, the primary infective agent, acts. When introduced into the body the bacillus begins to digest the proteids; the products of digestion cause a local œdema containing in solution (like other pathological effusions) a large quantity of proteids which are outside the metabolism of the body, and which therefore serve as a suitable food for the bacillus. The absorption of the digested products from the local œdema, and from the other parts of the body in which the bacillus grows, produces the symptoms of the disease, and it is to the gradual accumulation of the poisonous anthrax base that the stupor ending in coma and death is due. These bodies are the specific products of the bacillus, and are readily recognised either in a cultivation or when separated from the tissues of an animal dead of the disease.

DIPHTHERIA.

The general conclusion from the study of the chemistry of anthrax was that two classes of products were formed from the proteids of the body by the bacillus, one belonging to the digested proteids—viz., albumoses,—the other to the non-proteid class, a definite organic base with a specific action. With these results in mind the work on diphtheria was begun, but a somewhat different method of investigation was adopted. The tissues of patients dead of diphtheria were, in the first instance, chemically investigated before an attempt was made to isolate the products of the bacillus diphtheriæ. In the search for specific poisons in diphtheria the aim was perhaps theoretically simpler than in the case of anthrax, for in diphtheria there is the peculiar palsy which follows the disease, and is so closely associated with it that it is more properly considered a symptom, and not a sequela. All facts point to the diphtheritic membrane as the seat of origin of the disease, so that it was examined chemically, as well as the blood, spleen, and kidneys.

Cases of diphtheria examined.—In all eight cases of diphtheria were examined, six of which are shown in the following table. They all occurred in children.

No. of Post-mortem Exams.	Hours after death.	Age of Patient.	Duration of disease.	Extent of diphtheria.	Other lesions.
1	3½	1 year	6 days	Laryngeal	—
2	3	5 years	8 ,,	Nasal, pharyngeal, & laryngeal	—
3	6½	4 ,,	10 ,,	Tonsillar	1 small suppurating gland below jaw
4	12	1½ ,,	9 ,,	Pharyngeal and laryngeal	—
	4	3½ ,,	7 ,,	Pharyngeal and laryngeal	Broncho-pneumonia
	13½	8 ,,	4 ,,	Naso-pharyngeal	—

Cases 2, 4, 5, and 6 showed at the post-mortem examination the typical diphtheritic membrane, and a microscopical examination exhibited the typical structure of the membrane with the presence of the bacillus diphtheriæ in the superficial layers. Case 6 might be classed as one of malignant diphtheria from its rapid course with high fever and great prostration. Cases 1 and 3 differed from the others in the following respects. In Case 1 there was at the post-mortem examination nothing visible to the naked eye as the cause of death. There were a few small erosions on the under surface of the epiglottis and in the upper part of the larynx, but no membrane, nor had membrane been observed during life. The pharynx and fauces were normal. On a microscopical examination a few minute flakes of membrane were found in the larynx with the diphtheritic bacillus near the free surface of the membrane. During life the child had suffered from a croupy cough, and died in dyspnœa after tracheotomy. This case resembles those described as croup. Case 3 showed at the post-mortem examination congestion and erosion of the tonsils and congestion of the pharynx; there was no membrane, and cultivations of the throat yielded only micrococci, and not the bacillus diphtheriæ. Membrane was, however, present in the throat on admission into the hospital. These six cases, therefore, represent the different classes of cases which die; those with typical membrane in the nose, pharynx, or larynx, as Cases 2, 4, 5, and 6, some of which may have broncho-pneumonia as well; those in which the disease is limited to the larynx, and in which membrane is discovered only microscopically; and, lastly, cases in which the membrane, as such, has disappeared, leaving a congested condition of the throat, and in which the disease is associated with a secondary pus infection of the lymphatic glands below the jaw.

Method of examination of tissues.—In the separation of poisonous products from the tissues or from a culture of a micro-organism, the same method is applicable, except that the culture has first to be freed from bacilli. With the tissues, for example, the spleen and other organs are finely minced and placed in rectified spirit, the blood is also placed in rectified spirit, and the mixtures are allowed to stand until all the ordinary proteids are coagulated. They are then filtered and the residue is extracted with cold distilled water until nothing more dissolves. All the extracts are mixed together, evaporated at 35° C. to a small bulk, and thrown into absolute alcohol. This precipitates most of the albumoses, some deutero-albumose remaining in solution. After standing the alcohol is poured off the precipitate, evaporated to dryness at a low temperature, and extracted by absolute alcohol until nothing more dissolves. The residue left is deutero-albumose with mineral salts. All the proteid is mixed together, dissolved in a small quantity of water and precipitated by alcohol, the process being repeated several times to remove any traces of bodies soluble in alcohol and the excess of mineral salts. At the last precipitation the precipitate is allowed to stand under alcohol for from six weeks to two months, after which the alcohol is poured off and the precipitate dried *in vacuo*; so that from first to last the products are in contact with no reagent but pure alcohol, and are never heated to above 40° C. The resulting product is a light-yellowish brown powder, which yields nothing to alcohol, ether, or chloroform, and which keeps indefinitely if preserved in a dry atmosphere. It is soluble in water, cold or boiling; its solution being yellowish, sometimes faintly acid or nearly neutral. It consists almost solely of deutero-albumose, a small amount of proto-albumose being also present. There is no peptone in it. It gives all the ordinary actions of proteid and a well-marked biuret reaction. It is completely precipitated from solution by saturation with ammonium sulphate; nitric acid gives a slight precipitate, which is greatly increased if sodium chloride be added to the solution. In fact, this proteid powder is chiefly deutero-albumose, giving reactions similar to those of peptic deutero-albumose. The alcoholic extract of the tissues is strongly acid, and contains an appreciable quantity of free fatty acid, and also of another organic acid, which is separated from the first by its insolubility in chloroform. This organic acid is readily soluble in water and absolute alcohol, and quite insoluble in ether, chloroform, and benzene. It is a yellowish amorphous body, which becomes a deep brown on being made alkaline. Its further chemical characteristics are not at present investigated. In the tissues of none of these patients was there any organic base or alkaloid present.

Amount of these products present.—An attempt was made in some of the cases examined to estimate the amount of albumoses and alcoholic extract (that is, organic acid) present in the blood and spleen. The weights given are only approximate, as there is such a great loss of the substances during purification.

No. of case.	Seat of Disease.	Albumoses in grammes.			Alcoholic Extract.
		Blood and Spleen.	Blood only.	Spleen only.	Blood and Spleen.
1	Larynx	0·974	..	..	0·271
3	Tonsils	0·5955	..	..	..
4	Pharynx and larynx	..	0·149	..	0·167 (blood only)
5	Pharynx and larynx	0·805	0·450	0·355	0·455
6	Naso-pharynx ..	..	trace	0·715	..

From this table the following conclusions may be drawn:—1. The albumoses are always associated with the presence of the organic acid, and the amount of albumoses is much greater than that of the acid. This is a fact of great importance in considering the relative physiological action of the two classes of substances. It will be noticed, too, that in Case 1, which occurred in a child only a year old, nearly a gramme of albumoses was obtained from the blood, spleen, and kidneys, which represents a much larger quantity really existing in the body, owing to the large amount lost in purification. 2. In two of the cases the greatest quantity of albumoses was present in the spleen—in Case 1, in which the organ was not enlarged, and in Case 6, in which only a trace was found in the blood and 0·715 gramme in the spleen. Similarly from the spleen a larger amount of the acid body was obtained than from the blood. The spleen is, in fact, the chief repository of the diphtheritic poison in the body. 3. It is also noticeable that in Cases 1 and 3, to which attention has been already drawn, as differing from the typical cases of diphtheria seen on the post-mortem table, the same bodies were found as in the typical cases of diphtheria, and it may be at once stated that the results of the physiological action of these bodies were the same in all the cases. Cases 1, 3, 5, and 6 were those in which the products were used for physiological experiments. We might, therefore, sum up the chemistry of the tissues in diphtheria by saying that two classes of substances are present which are abnormal to the body, one belonging to the group of digested proteids—namely, albumoses; the other an organic acid. Contrasted with anthrax, it is seen that, whereas the bacillus anthracis produces albumoses and an organic base, in diphtheria we have albumoses and an organic acid. The albumoses of diphtheria cannot be distinguished from those of anthrax or peptic digestion by chemical means. Their physiological effect—a test more delicate than any chemical reaction—is the only method by which their specificity is made evident.

Physiological action of the albumoses found in the tissues in diphtheria.—1. When subcutaneously injected the diphtheria albumoses produce a local œdema, which in one case came on in two hours, spread rapidly for twenty-four hours, and rapidly diminished; so that in thirty-six hours it had practically gone and left no trace behind. It is a clear œdema, unaccompanied by any naked-eye congestion of the part, and not followed by any necrosis. 2. A more important effect is that on the body temperature. The subcutaneous injection of 0·256 gramme per kilogramme of body weight in a guinea-pig produced only an irregularity of the temperature and no well-marked rise—a result in marked contrast to the similar experiment with anthrax and peptic albumoses, which I have already demonstrated. When injected into the circulation of rabbits, however, these albumoses will produce fever.

Rabbits (precautions).—It is necessary to premise that in all experiments on the effect of the intravenous injection of these proteid poisons certain precautions must be taken in order to ensure that the animal you use for experiment is a healthy one. My usual practice is to isolate an animal and to take its weight, then to observe its temperature three or four times daily for a week or more. If during this time the animal gains in weight, and if the rectal temperature does not at any time rise to 103°, or for one day does not keep at about 102·5°, the animal is used for experiment. If such precautions are taken, both time and animals are saved, and greater accuracy in the experiments is secured. There is one disease in rabbits—viz., spinal curvature causing paraplegia—which is not excluded by the precautions which I have enumerated; but this disease is a very definite one, and readily recognised.

Intravenous inoculation, single doses.—In one animal a dose of 0·117 gramme per kilogramme of body weight produced a well-marked rise of temperature on the day of inoculation, and a slight degree of fever lasting two days more. Nothing further happened to this animal. It did not get paralysed, and when killed in ninety-four days it was fat and well nourished. In another animal a dose of 0·122 gramme per kilogramme of body weight produced a rapid fall of temperature, and death in three hours. Paralysis of the hind limbs occurred in one hour and a half, and was followed by coma. An examination made just after death showed a pinkish colouration of the lungs, due to congestion, and pallor of the spleen. There were no ecchymoses and no effusion. The blood was profoundly altered; it was dark and fluid, and was slow in coagulating. A small quantity put into a watch glass did not set for over fifteen minutes. Normal rabbit's blood begins to coagulate in from half a minute to one minute and a half. The retardation of coagulation observed in this instance is not peculiar to diphtheria products, but is observed also with the ordinary peptic albumoses.

Intravenous inoculation: multiple doses.—The effects following the intravenous injection of the diphtheria albumoses in divided doses is much more important than similar experiments with single doses. With multiple doses one imitates, imperfectly it is true, the course of events in the natural disease; moreover, as is well known, multiple small doses of a poison have a more powerful effect than a simple large doses.

Intravenous Injection of Diphtheria Albumoses in Rabbits in Multiple Doses.

Weight of rabbit in grammes.	No. of case of diphtheria.	No. of doses.	Total dose per kilogramme of body weight.	No. of days before death occurred.	No. of days before paralysis occurred.
1100	5	2	0·136 gramme	7	2
1970	5	2	0·153 ,,	11	6
970	6	3	0·157 ,,	10	7
1565	3	2	0·100 ,,	Killed in 24 days.	20
1200	6	2	0·083 ,,	Recovery in 54 days.	8

The doses were given, as a rule, on successive days; in one case on the same day. The first symptom noticed after the inoculation is fever, which in some cases is great and in some slight. In the first animal the fever lasted during the seven days it lived. This is the only instance of such an occurrence in any of the animals. In the second animal, in which the two doses were given on the same day, the fever lasted only during that day and was very slight. In the fifth animal the fever lasted about three days after the inoculation, and was moderate in degree. The effect on the body temperature is therefore a very varying one; but whether these animals have slight or great fever, they all show a more definite symptom—that is, a paresis of the muscles. In the first animal, for example, which had high fever, paresis of the left leg appeared on the second day; it was not used so much as the right leg in jumping. The paresis was more marked on the fourth day, both legs were affected on the fifth day, and on the seventh day there was paresis of all the limbs. There was no complete paralysis, for just before death the animal could still move when touched, although it only hobbled a few paces. The second animal showed paresis of the right foreleg on the sixth day, and on the ninth day this extended to the other foreleg. There was a general weakness of the muscles until death on the eleventh day. In the third animal, with a moderate degree of fever lasting six days, a general weakness of the animal appeared on the fifth day, and a definite paresis in the hind limbs on the seventh day. This increased till death. The fourth animal, also with moderate fever, but with a smaller dose than the three just mentioned, showed only a slight general weakness for twenty days. On the twentieth day the paresis was definite in the hind legs; the animal was indisposed to move, and could not jump vigorously; the respiration was extremely rapid. The animal, however, recovered from the respiratory symptoms, and was killed on the twenty-fourth day. The fifth animal showed a slight continued fever after the second dose, which passed off in five days. Weakness in the hind legs appeared on the second day. On the eighth day the hind legs were much weaker, especially the left one, which was held slightly abducted. It continued in this state till the nineteenth day, when almost suddenly it became much worse. Attempts at walking and jumping resulted in an irregular movement, which carried the animal some distance forwards, when it stopped with limbs outstretched. The breathing was extremely rapid, and there were occasionally slight convulsive movements of all the limbs, which were possibly of respiratory origin. This serious condition of the animal passed off, and it regained a great deal of power in its limbs. The condition just described as passing off in this animal, which had the smallest dose, is the mode in which the other animals, which had the larger doses, died. It is, so to speak, the culminating point of the paresis which, although more marked in certain limbs, is always general, affecting the trunk muscles as well

Digitized by Google

as those of the limbs. When it comes on with the larger doses it usually lasts twenty-four hours before the animal dies. It is, as shown by the post-mortem examination, partly respiratory and partly cardiac in origin. From the injection, therefore, of the diphtheria albumoses a paresis of the muscles is produced which may be most marked in one limb, but is always general and progressive. It is associated with an affection of the respiration as shown in the rapidity, or in some cases slowness, of breathing during the attacks described, which may pass off if the dose be small enough. With this paresis there is no special wasting of the muscles; even when the limb of one side is more paretic than that of the other, it does not waste to a greater extent. As regards loss of sensation, I did not attempt to estimate it, as the animals were rabbits. No affection of the pupil was noted in any of the animals. With the large doses the knee-jerks were found diminished after some days, but they never completely disappeared. When one hind leg was more paretic than the other, the knee-jerk on that side was diminished.

Loss of weight.—Although the muscles do not specially waste, there is a general loss of weight, which is the more marked the larger the dose.

Table of Loss of Weight.

Original weight in grammes.	Weight at death.	Proportional loss of weight.	No. of days before death occurred.	Fever period.	Dose of albumoses per kilo.
1100	970	⅛	7	7 days	0·136
1970	1520	¼	11	1 „	0·153
970	530	½	10	6 „	0·157

It will be noticed that the larger the total dose the greater the wasting which is produced. With the largest dose given the wasting was enormous, being nearly one-half of the original body weight. This wasting is not proportional to the fever, as it goes on after the fever has subsided. This is seen in animals 2 and 3, in one of which, with fever lasting only one day, one-quarter of the body weight was lost; and in the other, with fever lasting six days, one-half of the body weight was lost. With the smaller doses given, although the paresis was well marked and the respiratory troubles very manifest, the loss of weight was much less than in the animals shown in the table. Thus the animal with the total dose of 0·100 gramme per kilogramme of body weight showed on the eleventh day a loss of one-tenth of its body weight, after which it rapidly increased in size until it was killed (on the twenty-fourth day), while the animal with the total dose of 0·083 gramme per kilogramme of body weight showed in eighteen days a loss of only one-sixtieth of its body weight, after which it rapidly surpassed its original weight by 100 grammes, and subsequently showed only slight fluctuations in its weight. In these cases also the loss of weight is proportional to the dose of albumoses, and not to the fever.

Diarrhœa.—This is a symptom noticed only with the largest doses, and may last several days. It is watery and non-sanguineous. One of the most striking features of the action of these albumoses is their prolonged effect. The fever may last a long time; the paresis produced may be rapid in onset, but is slow in progress, and the general wasting produced is slow and prolonged.

Post-mortem examination.—That the symptoms described are really due to the action of these diphtheritic albumoses is evidenced by the post-mortem examination. That the animals did not die from the accidental introduction of a pathogenous micro-organism is shown by the fact that neither a microscopical examination of the organs of the body nor cultivations of the blood and spleen on agar and gelatine showed the presence of any such micro-organisms. The liver, spleen, and kidneys were, to the naked eye and to microscopical examination, normal. The lungs, lymph glands, and supra-renals were normal. In only one instance was subcutaneous œdema found; that was in the first animal, in which there was a large amount of œdema over the abdomen. As this was absent in the other animals, it was looked upon as an accidental effect of the poison. The albumoses used in inoculation were free from micro-organisms; the mode of preparation ensures this, since, from their removal from the body until they are dried, they are always in contact with an excess of pure alcohol, and when dried they are not touched except with sterile instruments, and are preserved in a sterile bottle in a dry atmosphere. All instruments used in the experiments are also sterilised, so that the effect of bacteria in producing the symptoms described is definitely excluded. But that the albumoses were acting in the body while the animal was alive is shown by the condition of the blood after death. It has already been mentioned that the blood was slow in coagulating in the animal which died in three hours after a single dose. In the animal which had the largest dose of the albumoses in three doses the blood was found in a similar condition. The animal died during the night, and the blood drawn from the right ventricles at 10 A.M. was liquid and of a lighter red than venous blood. In twenty-five minutes, at the temperature of the laboratory, a small amount placed in the watch glass began to coagulate, and was completely set in two hours. This slow coagulability of the blood, which is a well-known feature of the action of albumoses on the blood, showed that the diphtheria albumoses were actually present in the circulation in this case ten days after inoculation. But even in the animal which was killed twenty-four days after inoculation the blood was found slow to coagulate, commencing to set in about fifteen minutes, when removed one hour after death. This condition, however, was not found in another animal which died in eleven days after the inoculation of two doses of 0·153 gramme per kilogramme of body weight; but in this instance the two doses were given on the same day, and this fact, together with a difference in the rate of excretion in different animals, may show that the albumoses were not in sufficient quantity in the blood to retard coagulation, but were present in sufficient amount to produce the other symptoms of diphtheria albumoses—viz., the paresis and loss of weight. The condition of the blood in these animals appears to me to be extremely important, as it helps to explain why diphtheritic paralysis in man can occur sometimes after the acute disease is past.

ABSTRACT OF THE

Milroy Lectures

ON THE

PHYSICAL AND MENTAL CONDITION OF SCHOOL CHILDREN.

Delivered at the Royal College of Physicians, London, March 8th, 10th, 15th, and 17th,

BY FRANCIS WARNER, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE III.

RESULTS OF INSPECTION OF 50,000 CHILDREN SEEN IN 106 SCHOOLS.

The classes and groups of children described.—The study of the principles and methods of procedure to be employed, and practice in making observations and in describing them, were so far advanced in 1888 that a committee was formed by the Psychological Section of the British Medical Association, and, in conjunction with Dr. Hack Tuke, Dr. Fletcher Beach, and Dr. Shuttleworth, Dr. Warner made observations on 5000 children in fourteen schools, and published a report.[1] It should here be said that the observations of 1888–9 are incorporated in the larger report of 1890–92. This first inquiry, and the subsequent arrangement of cases in groups, afforded valuable experience, and gave many useful hints as to how the work should be further extended, and also as to the best methods of keeping the records and the kind of results to be looked for. Following the publication of this first report, a special committee was appointed by the Charity Organisation Society, including representatives of the older committee, and a report has been prepared on 50,000 children seen: Boys, 26,884; girls, 23,143.

Group 1. Normal or average children.—Boys 21,315, girls 19,536. Percentages on numbers seen: boys 79·3, girls 84·5. Such children are the average as presenting no visible defects or abnormal nerve signs, and not being reported as dull at lessons.

Group 2. Children presenting some deviations from the

[1] Brit. Med. Jour., July 27th, 1889.

Digitized by Google

normal, of whom notes were accordingly taken.—Boys 5579, girls 3607—total 9186 Percentage on numbers seen: boys 20·7, girls 15·5—total 18·3. Schedules were filled in for each of these cases; their varying conditions have been analysed, and they will now be presented in groups or classes.

Group 3. Children presenting no defects in development or abnormal nerve signs, but reported as dull by the teachers.—Boys 185, girls 134—total 319. Such cases present good physical development and a sound condition of brain as indicated by motor action. It appears that the brains of these children, though capable and healthy, had but little power for school work. It is important to differentiate such pupils from those with defective conditions.

Group 4. Children feeble minded, or exceptional in mental status.—Boys 124, girls 110. Of these cases, 2 were idiots, 46 imbeciles or definitely mentally wanting; 12 were mentally exceptional, wanting in moral faculty, or liable to mental attacks; 174 are entered as "feeble minded," or defective in mental capacity short of actual imbecility; probably many of them would on further examination be found imbecile, although some may be capable of great improvement.

Group 5. Epileptics, and children with history of fits during school life.—Boys 36, girls 18—total 54. These cases were inquired for in every school, and in some instances children not attending school were sent for by the teachers. Any case with a history or indications of fits during school life was recorded for what it may be worth; a list of these cases has been published.[2] It would appear that most epileptic children are absent from school. Of the cases given, 5 boys and 5 girls were mentally defective.

Group 6. Children crippled, paralysed, maimed, or deformed (not eye cases).—Boys 155, girls 84—total 239. These children varied greatly in brain power; some were mentally bright, others dull. They also varied in conditions of health. The conditions of disease causing crippling were in various stages, and many of these children were capable of work and play. Five boys and five girls were mentally defective. Cripples from congenital defect: Boys 7, girls 9—total 16. Cripples from disease or injury: Boys 88, girls 53—total 141. Cripples from paralysis: Boys 60, girls 22—total 82.

Group 7. Children deaf, or partially deaf.—Boys 34, girls 33. These numbers do not include 51 children seen in a special school, of whom an account was given in an early report. Tests for hearing were not commonly used, but a child found deaf was noted. There were some deaf and dumb in the day schools.

Group 8. Eye cases.—Boys 836, girls 637. Tests for vision and errors of refraction were not used, and ophthalmia was passed over, but when the eyes were looked at obvious defects were noted. Ophthalmia was seen in some day schools. There were of squint cases 807, some requiring operation, many temporary, but only 276 children in all used convex glasses; 48 used concave glasses. The group shows what a large amount of ophthalmic work is needed among children.

Group 9. Children pale, thin, delicate; nutrition low.—Boys 1030, girls 973. The most obvious fact concerning these children was that 733 of the boys and 726 of the girls presented some defects in development. No inquiries were made as to the feeding of these children, but it may be assumed that among the upper grade schools and in the resident schools food was sufficient; still the development cases were of low nutrition there also. Among the 50,000 cases the percentage of low nutrition was for boys 3·8, for girls 4·2, and among the development cases it was for boys 20·2, for girls 32·0.

Group 10. Children presenting defects in development.—Boys 3616, girls 2235. Conditions of mal-development form the largest class of visible defects observed, and as signs easily recognised and capable of description and classification they stand prominently forward as pathological conditions characterising portions of the child population. Analysis and comparison of cases show the developmental signs to be of different value and importance; to demonstrate this the correlation of each sign has been determined (see Interim Report published); from the point of view of estimating potential mental capacity these signs are of value only in as far as experience gained in observation shows their average correlation with cerebral or mental defects. The defectiveness in the make of a child is more strongly indicated when two mal-developments are present; this was noted in 1240 boys, 683 girls; their correlation was higher than for a single defect—with nerve signs 45, low nutrition 31, dulness 60 per cent.

Group 11. Cases presenting nerve signs.—Boys 3413, girls 2074. Abnormal nerve signs are largely correlated with defects in development—that is to say, some malproportion in the parts of the body is largely associated with a tendency to ill-balance among the nerve centres. The significance of these signs varies in two directions: some indicate an over-mobile nerve system, the centres tending to separate and spontaneous action, not well under control through the senses, of which finger-twitching is the type; and a second set which indicate low class brain development. These are mostly repeatitive uniform movements, athetoid in type, and represented by chronic over-action of the frontal muscles and repeated grinning.

Group 12. Cases of rickets.—Boys 157, girls 30—total 196. With nerve signs: Boys 54, girls 15—total 69. With low nutrition: Boys 32, girls 13—total 45. With mental dulness: Boys 64, girls 10—total 74. Probably more children were or had been rachitic than those registered; when the conditions seen in the bones left no doubt, the case was registered accordingly, but the body could not be examined in detail under the conditions of this inquiry. It seems that a great character about the conditions termed "rickets" is the malproportion of growth in the skeleton, especially about the cranium. It is shown that defects in development other than cranium and palate were found in 58 boys, 11 girls—total 69 cases. The pathological question might be raised whether a large proportion of the cases registered as "cranial bosses"—a sub-group of the cranial abnormalities amounting to boys 495, girls 127: total 622—were not really cases of rickets. These rachitic children are badly proportioned. Cranial abnormalities: Boys 143, girls 26—total 169. Palate defective: Boys 23, girls 8—total 31. Cranium and palate defective: Boys 21, girls 6—total 27. Small in growth: Boys 10, girls 5—total 15.

Group 13. A group of cases with defects in development: Abnormal nerve signs and low nutrition.—Boys 412, girls 381—total 793. With mental dulness: Boys 192, girls 157—total 349. This group appears, in fact, to present a special class of development cases, in which the inheritance has produced not only visible malproportions or proportioning in the body, but also a constitutional tendency to low nutrition, and a state of nerve centres ill balanced or badly acting. Such children may be said to be delicate, and 44 per cent. of these were reported by teachers as dull. These children when dull are included in the group that appears to need special care or training.

Group 14. Children reported by the teachers as dull in school.—In every case recorded the teachers' opinion concerning the child's mental capacity was asked for and taken down as evidence. The number of dull children was: boys 2216, girls 1463—total 3679. Their correlations are given in full in a table. Of these dull children, defects in development or abnormal nerve signs were found in 3266 cases.

Group 15. Children that appear to require special care and training.—It is not intended to imply that these children cannot be provided for in day schools; but they need to be provided for, and it might be well that they should be marked on the school register, and their attendance and progress noted by the managers. The group includes children feeble minded or mentally exceptional (Group 4); epileptic, cripples and "the development cases, with low nutrition and nerve signs, who were reported as dull mentally." The group as thus arranged, allowing for overlapping cases, contains 817 children (boys 473, girls 344), or 1·6 per cent. on the 50,000. Of the number given, 165 are included on physical grounds as not being mentally dull.

Group 16. Children presenting abnormal nerve signs without defects in development.—Boys 1438, girls 978—total 2416. In these cases there are no indications of defect in development to account for the nerve signs, and they appear to be due to other causes; they are slightly more frequent among the resident children and among the upper class children than in the average day schools, so that low feeding does not appear as a potent cause. It is probable that in this group we have the children of normal make who are ill-trained, neglected, and over-pressed by the stress of life. These seem to be the children most improvable by altered

[2] See Interim Report on Schools, Charity Organisation Society.

Digitized by Google

conditions and appropriate training. Many are of ill balance and nervous; 39 per cent. of them were dull.

Group 17. Children presenting development defects with abnormal nerve signs.—Boys 1975, girls 1096—total 3071. With low nutrition: Boys 733, girls 726—total 1459. With mental dulness: Boys 835, girls 475—total 1310. These children appear as cases with malproportioning of the body and ill-balanced nerve centres. The percentage of dulness among them is higher than among either the "development cases" or the "nerve cases."

Group 18. Children presenting development defects without abnormal nerve signs.—Boys 1641, girls 1139—total 2780. These development cases, with a well-regulated nerve system, present less dulness than the last group, showing the importance of observing nerve signs. Of development cases with nerve signs, 43 per cent. dull. Of development cases without nerve signs, 35 per cent. dull. Comparing groups of schools, the percentages go against the residents as compared with day schools, except as to nutrition. Again, comparing schools of upper and lower grade, the conditions found are in favour of the lower class. Lastly, among the English children development defects are found in 10·8 per cent., among Jews 7·5 per cent., among the Irish 20 per cent.

The lecture was illustrated by tables and charts.

MICROCOCCUS PNEUMONIÆ CROUPOSÆ.

BY GEORGE M. STERNBERG,
LIEUT.-COLONEL AND SURGEON, UNITED STATES ARMY.

Synonyms.—Microbe septicémique du salive (*Pasteur*), *Coccus lancéolé* (*Talamon*), *Micrococcus Pasteuri* (*Sternberg*), *"Pneumococcus of Fränkel," Diplococcus pneumoniæ* (*Weichselbaum*), *Bacillus salivarius septicus* (*Flügge*), *Streptococcus lanceolatus Pasteuri* (*Gamaleia*).

THE object of the present brief paper is to call attention to the earlier researches relating to the important pathogenic micrococcus to which it refers. This seems desirable at the present moment, inasmuch as the distinguished author of the Croonian lectures, recently published in THE LANCET, has given an account of the history of the micrococcus in question, in which he fails to recognise my priority in its discovery. He says:—"Its history is as follows. In 1881 M. Pasteur observed to his surprise, in inoculating a rabbit with the saliva of a child affected with hydrophobia, that the animal died rapidly of septicæmia. Subsequently, Dr. Sternberg[1] of Washington, having observed that the inoculation of pneumonic sputum induced in the rabbit symptoms similar to those observed by Pasteur,[2] repeated the experiment with his own saliva. As this animal also died of septicæmia, he was led to investigate the subject bacteriologically, and found that in all the animals inoculated the same microzyme occurred, and that it corresponds with Pasteur's description of the 'microbe septicémique du salive.'" Now, as a matter of fact, and of record, the present writer discovered the micrococcus in question in the blood of rabbits inoculated with his own saliva, in the city of New Orleans, in September, 1880, three months before Pasteur discovered it (December, 1880) in the blood of rabbits inoculated with the saliva of a child which died of hydrophobia in one of the hospitals of Paris. At the date referred to I was not able to follow up my experiments immediately, as I was engaged in another investigation. But they are recorded, with the date upon which they were made, in my special report to the National Board of Health on "Experimental Investigations relating to the Etiology of the Malarial Fevers," which was submitted some time before the publication of Pasteur's note referred to by Dr. Burdon-Sanderson, and was published in the National Board of Health Bulletin, vol. iii., Washington, 1881–82. Impressed with the surprising fact that my saliva contained a pathogenic micrococcus which quickly proved fatal to rabbits inoculated with the fluid containing it, I went to Philadelphia in January, 1881 (before the publication of Pasteur's first communication), for the express purpose of making further investigations with reference to this micrococcus in the laboratory of the medical department of the University of Philadelphia. "Here eleven inoculation experiments demonstrated (*a*) that the virulence noted was not due to season or locality, as the same result followed inoculations made in Philadelphia during the winter months as had been obtained by similar inoculations in New Orleans during the heat of summer; (*b*) that this virulence was not an individual peculiarity, inasmuch as eleven rabbits inoculated with the saliva of six different persons gave eight deaths and three negative results." In March, 1881 (still before the publication of Pasteur's first communication), I resumed my experiments in the biological laboratory of Johns Hopkins University, Baltimore, and, by the inoculation of pure cultures obtained from the blood of infected rabbits, proved that the fatal septicæmia induced in rabbits by inoculating them with my saliva was beyond question due to this particular micrococcus. I also determined many of its biological characters, accurately described its morphology, and made photo-micrographs showing it in the blood of an infected rabbit. The results of this investigation are published in my paper on "A Fatal Form of Septicæmia in the Rabbit, produced by the Subcutaneous Injection of Human Saliva"[3] The publication of this paper was considerably delayed after I had completed my research, and in the meantime Pasteur had published his "Note sur une Maladie nouvelle provoquée par la Salive," referred to by Dr. Burdon-Sanderson.

My earlier researches were followed by others, in which I used this micrococcus as a test of the comparative value of various disinfecting agents,[4] and in the course of which I determined various points relative to its biological characters. In January, 1885, I made a series of experiments with pneumonic sputum which led me to the identification of the oval coccus, usually in pairs, found in this material with the micrococcus previously isolated from my own saliva. In the paper in which I gave an account of these experiments[5] I named the micrococcus in question "Micrococcus Pasteuri," a name which has not been generally accepted, and for which I now propose to substitute the name placed at the head of this paper, "Micrococcus pneumoniæ crouposæ." In my paper last referred to, which was read before the Pathological Society of Philadelphia in April, 1885, and published in the *American Journal of the Medical Sciences* for July of the same year, I say: "It seems extremely probable that this micrococcus is concerned in the etiology of croupous pneumonia ..... But this cannot be considered as definitely settled by the experiments which have thus far been made upon the lower animals." Fränkel's first paper[6] relating to the presence of this micrococcus in pneumonic exudate was published shortly after my paper last referred to. Since the date last mentioned the extended researches of Fränkel,[7] Weichselbaum,[8] Netter,[9] Gamaleia,[10] G. and F. Kemperer,[11] and others have established the fact that this micrococcus is the usual cause of croupous pneumonia. Recognising this, we propose hereafter to designate it "micrococcus pneumoniæ crouposæ." This corresponds with the nomenclature adopted by Flügge in describing other pathogenic bacteria—e.g., micrococcus gonorrhœæ, bacillus typh. abdominalis, spirillum choleræ asiaticæ. The name "diplococcus pneumoniæ," which has been adopted by most German bacteriologists, and following them by many English and American authors, is objectionable, because this coccus is not truly a diplococcus, although commonly seen in pairs and preparations made from pneumonic exudate or from the blood of an infected rabbit. But it is also frequently seen in short chains of three or four elements, and in cultures upon nutrient agar it often forms long

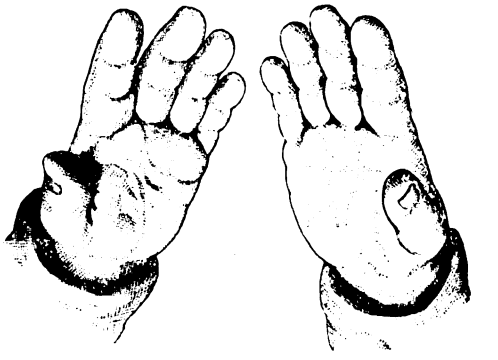
chains. It is therefore more properly called a streptococcus. Gamaleia calls it "streptococcus lanceolatus Pasteuri." We prefer, however, the more general generic name "micrococcus," and do not consider it necessary that the name should be descriptive of the mode of grouping of the cocci. It may be questioned whether "diplococcus" as a generic name is entitled to a place in our nomenclature. It simply represents a form of association which is common to all micrococci, although more persistent in some than in others, and which results from their multiplication by binary division. Now some of the so-called diplococci multiply in one direction only, forming pairs, and longer or shorter chains, as in the case of the micrococcus under consideration; while others multiply in two directions, forming pairs and, by transverse division, groups of four—e.g., diplococcus citreus conglomeratus (Bumm) and diplococcus roseus (Bumm). Thus a most important generic character—division in one or two directions—is ignored by those bacteriologists who use the term "diplococcus" as a generic appellation. Again, some of the micrococci commonly described under the generic name "streptococcus" are seen, under certain circumstances, only or chiefly associated in pairs. We therefore object to the use of the term "diplococcus," as a generic name for micro organisms of this class, as being unscientific and misleading.

San Francisco.



A CASE OF ACROMEGALY.

BY ALFRED G. BARRS, M.D. EDIN., M.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN TO THE LEEDS INFIRMARY; LECTURER ON MATERIA MEDICA IN THE YORKSHIRE COLLEGE OF VICTORIA UNIVERSITY.

THE patient, A. W——, aged twenty-eight, laundress, was born near Brough in East Yorkshire, but latterly has lived at Altofts, near Normanton. Her father died at the age of forty-three (cause unknown). Her mother is living and well. She is the only child of the marriage. In childhood she had scarlet fever and measles, and in March, 1891, she had influenza. Menstruation began when she was just over eleven years old, and was quite regular up to two years ago, since when there has been total amenorrhœa. The menstrual discharge was always scanty, and never lasted more than a day. During girlhood, although she was well grown and developed in every way, she was never strong. She was always more or less short of breath on exertion, and always had a pain in the left submammary region; still, up to four years ago, she did not consider herself to be the subject of any definite complaint. Four years ago she began to feel certain disturbances in her hands, which she describes as "nasty prickly sensations and a feeling of swelling," and there is no doubt that the hands, feet, and face were at this time getting larger. The feet also felt as though "asleep," and she frequently dropped what she was carrying through being unable to feel it, as it were. The limbs are described as feeling heavy and powerless, and are always worse after exertion—such as a day's washing. She frequently finds herself unable to fasten her clothes on account of the numbness and clumsiness of her hands, though her handwriting is as good as ever it was. On account of the increasing size of the fingers she is unable to get a thimble large enough; the thimble which four years ago she could use with ease is now not quite large enough for the little finger.

She may be described as a big woman of peculiarly cheerful disposition and good intelligence. She weighs 16 st. 2 lb., and her general figure is such as that weight would indicate. She is distinctly round-backed, so much so that her chin is carried almost on her chest. She has the use of all her limbs with the qualifications mentioned above. She is a little short of breath on exertion. Her complexion is striking, and, with the changes in the facial contour, gives her a countenance very much like that of a Chinaman of her size. The voice is husky and distinctly masculine in character. There is always profuse sweating of the palms and soles, and that of the latter is distinctly offensive. This did not exist before four years ago. The appetite is not increased. There has been absolute amenorrhœa for two years. The generative organs were not examined. The hands present in a marked degree all the characteristics of acromegaly as described by Souza-Leite,[1] and contrast strangely with the natural, or almost natural, appearances of the other parts of the upper limbs (see Fig. 1). The whole hand is enlarged without any or little departure from the natural model, and of all the parts of the member the fingers show the greatest increase in size. The digits, showing well the sausage-shape, and the nails, which look too small for the fingers, are broader than they are long, flat, and show a well-marked tendency to longitudinal striation. The skin of the hands has a sodden appearance from the excessive sweating to which she is subject; it is soft and supple, of a

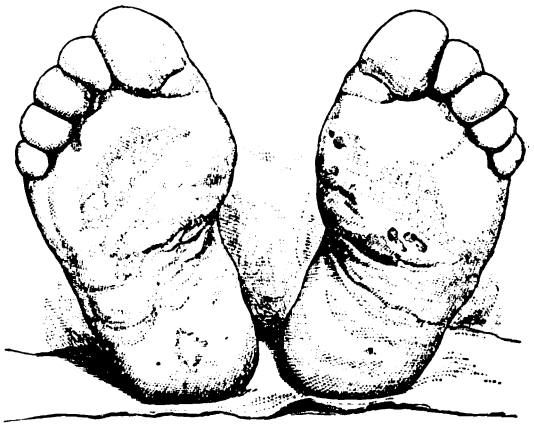


FIG. 1.

rather earthy tint, and shows a normal amount of folding about the joints. The enlargement clearly affects the bones as well as the soft parts; the latter, in the palm especially, are peculiarly abundant and loose.

The size of the nose, the heavy pointed chin, the broadening of the inter-malar measurement, and the eversion of the lower lip are very striking. She has a distinctly prognathous appearance in profile. The hair is very abundant and coarse. The ears are certainly large. There is no distinct change in the bony prominences of the cranium. The neck is short and thick. The skin is much folded about the angle of the jaw and behind the ear, and there are a number of small sebaceous cysts scattered

FIG. 2.

about the region in question. The feet also are characteristic, and present changes quite similar to those in the hands—that is to say, they are large, heavy, and thick, without much, if any, increase in their length. The soft parts of the sole are curiously redundant, giving rise to a marked exaggeration of the foldings natural to the part. The epidermis is here and there thickened, and apparently about to separate (see Fig. 2). The patella is much enlarged.

The following are selected from a large number of measurements made of the head and extremities: Height of patient, 167·5 c.m.; circumference of the neck between the

[1] De l'Acromégalie, Paris, 1890.

Digitized by Google

hyoid bone and upper part of thyroid cartilage, 36·5 c.m.; circumference of head, 57·5 c.m.; breadth of head from mastoid process to mastoid process, 15·5 c.m.; length of nose, 6 c.m.; greatest distance between outer surfaces of malar bones, 14·5 c.m.; lower jaw, vertical measurement, from free border of gums to lower part of symphysis, 4·50 c.m.; greatest length of ears, 6·50 c.m.; greatest breadth of ears, 3·45 c.m.; length of forearm from the olecranon process to styloid process of ulna, 26 c.m.; circumference of forearm at middle, 25 c.m.; circumference of forearm at wrist, 19 c.m.; length of hand from wrist to tip of middle finger, 20 c.m.; length of middle finger from palmar fold to tip, 9·1 c.m.; circumference of middle finger, 7·8 c.m.; circumference of little finger, 6·7 c.m.; antero-posterior diameter of middle finger, 3 c.m.; lateral posterior diameter of middle finger, 3·7 c.m.; length of nail of middle finger, 1 c.m.; breadth of nail of middle finger, 1·5 c.m.; circumference of hand without thumb, 23 c.m.; circumference of hand in obstetric position, with thumb, 28·5 c.m.; breadth of hand at metacarpo-phalangeal joint, 10·5 c.m.; vertical diameter of patella, 6·75 c.m.; greatest circumference of calf, 39 c.m.; circumference of ankle just above tip of internal malleolus, 26·5 c.m.; greatest length of foot, 25 c.m.; circumference over heel and instep, 37 c.m.; greatest width of foot, 10·5 c.m.; circumference of great toe, 10·5 c.m.; length of great toe-nail, 2 c.m.; length of great toe from proximal joint to tip, 7·5 c.m.; length of second toe from proximal joint to tip, 6·25 c.m.

These measurements were made in accordance with those used by Dr. Ross (after Marie), in his case published in the *International Clinics*, vol. i., 1891, with which they may be compared. The thorax is normal in shape, and there is no substernal dulness. The thyroid region presents no peculiarity. The general musculature is wanting in tone, but otherwise shows no deviation from normal. The tendon reflexes are normal. The cardio-vascular mechanism is normal. The urine is normal in quantity, and contains neither albumen nor sugar. So far as subjective symptoms are concerned, in addition to the sensation of numbness and pins-and-needles in the hands and feet, there is a fairly constant headache of not very great intensity. This headache comes on in paroxysms, and occasionally causes vomiting. The special senses are not complained of. My colleague, Mr. Secker Walker, was good enough to examine the eyes for me, and found the visual field and the fundus quite normal. Compared with many cases the development of the typical limb changes of acromegaly in this instance has been unusually rapid, and in this respect it resembles two interesting examples recently recorded by Guéniot and Sarmont.[2] These cases are illustrated by most beautiful photogravures. Souza-Leite[3] has collected from English literature six cases which he regards as true examples of acromegaly. One of these, published by Dr. Tresilian[4] under the heading "A case of Myxœdema," appears to me to be correctly classed by its author, and not to be an example of the condition described by Marie. Mr. Hutchinson[5] records a case, and says in the same publication for 1890 that he saw three cases in 1889. Mr. Ruttle[6] has recorded a genuine example with good photographs. Dr. Ross's case, previously mentioned, terminated fatally, and so gave the only opportunity which has occurred in this country for a demonstration of the morbid anatomy of acromegaly. A short account of the post-mortem changes found in this case was published in THE LANCET[7] by Dr. Judson Bury. The changes consisted in "a large pulpy tumour at the base of the brain excavating the sella turcica and extending from the optic chiasma (which with the optic tracts was much compressed) to the cerebellum. Microscopically, it had the appearance of a glioma. Each lobe of the thyroid was enlarged and contained a cyst. Some pendant masses of tissue attached to the front of the pericardium, similar to pieces of a persistent thymus, showed only fat cells under the microscope." Dr. Berkeley[8] records the last case with which I am acquainted. It occurred in the person of a negress aged sixty, the first example, Dr. Berkeley says, of the disease in the negro race, and the forty-fifth case on record.

LEPROSY IN MINNESOTA, U.S.A.[1]

BY CHR. GRONVALD, M.D.

NORWEGIANS began immigrating to America more than fifty years ago, most of them going to the North-Western States—Wisconsin, Iowa, and Minnesota,—where they and their descendants form a considerable part of the population. Some of these immigrants were from parts of Norway where leprosy is endemic, and among them were some lepers. Norwegian physicians, aware of this fact, followed, to study the disease on foreign ground. Among them was Dr. J. H. Holmboe, surgeon in charge of a leper hospital in Bergen. He came in 1864, and found twelve lepers, of whom two had the first symptoms after their arrival here. He thought their health better, probably, than it would have been had they remained in the old home. In 1869-70 Professor Wm. Boeck of Christiania, Norway (joint author with Dr. Danielsen of Bergen of "Traité de la Spedalskhed, ou Elephantiasis des Grecs, Paris, 1848," published by the Norwegian Government) published his conclusions in "Nordiske Medicin. Archiv," Band iii., No. 1. He found in the three States named eighteen cases of leprosy, of which nine had the first symptoms after their arrival in this country. All were proved to come from leprous families in the old country, except one, in which he suspected hereditary influence, although admitting the possibility of contagion. He ascribes all the cases to heredity, not believing the disease contagious. He thought lepers better off here in respect of their disease than they would have been in their own country. He says: "They have come away from the place where we see leprosy may originate spontaneously, and which certainly will favour its development when the disposition is inherited. They have settled on fertile lands, where they certainly have to work hard to make a living, but they generally undergo no hardships, as we in Norway understand the term. There is no work that can be compared with that done at the midwinter fisheries in open sea off the Finmack coast, or the hardships suffered while tending the cattle on the high mountain plateaux, which causes so often bring out the latent leprosy."

Since 1870, when the above was written, investigations have been continued in Minnesota as to the number of lepers, their condition, and that of their families. There are medical correspondents everywhere in the State, who report all suspected cases to the State Board of Health, which then makes particular inquiries through its standing committee on leprosy, composed, since 1872, of the writer and the Secretary of the Board. At this date (July 20th, 1891) there are eighteen lepers known to live in Minnesota, of whom ten have the anæsthetic and eight the tubercular form of the disease.

Anæsthetic cases.—In one the disease was first recognised at least five years ago; its duration in the other nine averages nineteen years. The two oldest of this class are, respectively, seventy and seventy-four years of age, and have had the disease more than twenty-three and seventeen years respectively; while two others, sixty and fifty years of age, have had the disease thirty and thirty-two years.

Tuberculous cases.—The average duration of the disease in these cases to date is eight years, while in one the disease was first recognised a year ago. The longest duration of the disease in these cases is sixteen and fourteen years, in persons forty and thirty-six years old. The experience in

[1] This communication has been forwarded by the courtesy of Dr. Charles N. Hewitt, Secretary and Executive Officer, State Board of Health, Minnesota, U.S.A., accompanied by the following explanatory remarks: "This Report by the Committee on Leprosy of the State Board of Health of Minnesota came too late for presentation to the late Congress. It relates in very conservative language the experience we have had for the last forty years with leprosy in Minnesota. In no other State that I know of are all known lepers registered and kept under observation, and all suspected cases carefully looked into. The history of these cases has been very thoroughly studied. No further isolation than the use of their own beds and utensils is required, and this their own good sense and that of their relatives, as a rule, secures. It must be understood that the State Board of Health and the local boards have abundant power to enforce the strictest isolation, if found needful; but up to date there has not been any occasion for the use of such power, as the disease is limited to the immigrants, and has never appeared in the descendants of lepers, nor in anyone born in the State. It is under constant and careful observation, and has been for the last eighteen years under the care of the State Board of Health. The facts here officially stated will interest the students of a disease about which a good deal more has been written than is actually known."

Digitized by Google

this country has not been very long, although it already includes several generations. Such as it is, some of its results are:—1. In no children or descendants born in Minnesota of lepers—there are great-grandchildren—has there been any sign of the disease discovered, although under frequent observation. 2. Up to date no leper has been born in Minnesota. 3. In many cases the disease was not recognised for a long time after the arrival of the persons affected in this country—how long it is difficult to state, as the first symptoms are obscure, not noticed, or misunderstood; but in every single instance the leper has some time had his home in some place in the old country where the disease was endemic, while in but a single case has the possibility of infection been pointed out, and that came from a locality in the old country that has been for years a nest of leprosy. These facts, as far as they go, seem to suggest that the disease in this country is not so easily acquired as in some other countries. Looking for the cause, some points present themselves for consideration.

1. New houses with new furniture and furnishings in a new country harbour no sources of infection, and the better economical condition promotes the sense of need for cleanliness both for health and comfort,—a cleanliness which seems in leprosy to be the main reliance against contagion. 2. The commonly dry and always windy climate of this great inland plateau, with its great and sudden changes of temperature, open as it is towards the Gulf of Mexico and towards the North Pole, may perhaps make it more difficult for the *materia peccans* to fix itself on persons and things. The hot summer that opens up the pores of the skin and drains the system that way, and the cold stormy winters acting on the body somewhat differently, may have influence in that direction. That the climate must have some influence in preventing the spread of the disease seems yet more probable when we remember that the early settlers, often with a large family of children, lived for a long time in small, close, and badly ventilated log houses, closer even than they were accustomed to in their old homes. Even if they did not bring with them such sources of contagion as unclean houses and old furniture, they at least had for some time old clothes, so that it would be a wonder if old and young could have observed the cleanliness necessary to prevent contagion if the effect of climate had not been to make contagion more difficult. It seems certain that the disease, once established, runs its regular course here as elsewhere, perhaps a little slower. 3. The change in the physical constitution of people who have lived here some time, the effect of acclimatisation and of other influences, may make the individual less susceptible to contagion. In 1888 Dr. G. Armauer Hansen of Bergen, Norway, the discoverer of the bacillus leprae, came to this country to study leprosy in the immigrated Norwegians and their descendants. He had taken the position in 1874 that contagion is the only source at present of leprosy, and that the disease is not hereditary. He gives the results of his investigations.[2]

"I cannot here relate all my observations in detail. I will only tell what I have found in regard to the occurrence, or rather the disappearance, of lepra in America (N.W. States). Of about 160 lepers who have immigrated into the three States named (Wisconsin, Iowa, Minnesota), thirteen are alive, whom I have seen myself, and perhaps three or four more. All the others are dead. Of all the descendants of lepers (and that includes the great-grandchildren of some of them), not a single one has become leprous. This is, in short, the result of my investigations."

SOME RECENT MODIFICATIONS IN OUR VIEWS OF ENTERIC FEVER AND ITS TREATMENT.[1]

BY M. A. BOYD, M.D., F.R.C.S.I., M.R.C.P.I.,
PHYSICIAN TO THE MATER MISERICORDIÆ HOSPITAL, DUBLIN.

SINCE Murchison wrote his classic treatise on Enteric Fever we have scarcely added anything clinically to the accurate and scientific description he gave of the disease. He covered in that description almost the entire ground in connexion with the disease and its history, and in the closeness of his reasoning as to its etiology he foreshadowed all that bacteriology has since discovered regarding it. In fact, it is only in its bacteriological aspect that any additions have been made to the subject, and it is from this side alone that any additional knowledge is likely to come which can finally determine the mode of its origin. The additional bacteriological data, however, we now possess have considerably narrowed the issues and enabled us to regard the disease from the standpoint of being an acute infective disease, which heretofore it was not considered, in which, like phthisis and pneumonia, a special bacillus plays the important part. Since that bacillus was discovered by Koch and Eberth, and its peculiarities and mode of growth studied, more especially by the latter observer, our views as to the etiology of the disease have considerably changed, and the time has, I think, now come when, taking advantage of the experiments of various other bacteriologists in addition, we may form more definite ideas as to its mode of propagation, to its prevalence at particular seasons, and the causation of the symptoms present in its various stages, as well as to suggest some rational means for treating it.

I shall first refer to the typhoid bacillus and its discovery. In 1880 Koch and Eberth almost simultaneously discovered in the intestines, the mesenteric glands, and lymphatics, and especially in the spleen, of patients dying of enteric fever a bacillus which, though frequently found in the intestines as the common bacterium termo, assumed at particular seasons, or owing to some alteration in the normal vital resistance of the individual, an acutely infective process, infiltrating the adenoid tissue and lymphatics of the intestine, accompanied by the chain of febrile phenomena we designate typhoid or enteric fever. Owing to the difficulty of finding a suitable nutrient medium on which to grow it outside of the body, this bacillus could not be differentiated from other bacteria inhabiting the alimentary canal, until Koch succeeded in isolating and growing it on dry gelatine plates. Since then all pathologists are familiar with its appearance and mode of growth. So far all experiments have failed in producing the disease from these cultivations by inoculation; but bearing in mind that it grows both as an aerophyte and as an anaerophyte, it may be innocuous in the former condition and infectious in the latter when in the alimentary canal, when the vital resistance of the tissues in that situation may be from some reason altered. What may produce these alterations I shall allude to presently. Gaffky, in his observations on this bacillus, has given us some valuable information as to its situation and growth. It is one of the few bacilli found to develop freely in water, and it grows abundantly in milk. He also found it in the soil through which water percolates, and it grew freely in all albuminous media. He also found it more abundant in all these media in the autumn than at any other season—a fact of considerable significance. If, however, this bacillus is found so frequently in the food we eat, the water we drink, and in our intestines, how, we may ask, is it that it does not infect the intestinal glands when present and produce enteric fever in every case? For we must all take it in at some time or another, if it is not already present in our intestines. With this question I may link two others: Why is it we do not suffer from pneumonia constantly, when we always carry about with us the germs of the disease in Fraenkel's diplococci? Or why not frequently suffer from circumscribed or diffuse suppurations, when the micrococci that produce them are frequently present in our blood and tissues? Why we do not recent investigations in bacteriology have made clear. Bacilli or micrococci are in themselves harmless, either in the blood or tissues, until the vital resistance of some tissue is lowered, from either functional alteration or injury, when they readily find a suitable soil in it on which to grow and multiply. It is by this growth and the chemical products generated during it that the mischief is produced, and the poisoning of the tissues around that are most susceptible to its action afford a further field for the growth of these micro-organisms.

Let me take first the experiments of a distinguished physiologist, and secondly the course of a fatal disease which clinically we are only lately becoming familiar with, to illustrate my meaning. Professor Kocher of Berne, in making experiments on animals by destructive injury to tissues down even to the marrow of bones with a hot iron, could not produce septic inflammation as long as the animal experimented on was healthy, but if he lowered the vitality

[2] Virchow's Archiv, Band cxiv, 1888.

[1] Read before the Medical Section of the Academy of Medicine in Ireland, Dec. 18th, 1891.

of it by feeding it on putrid matters, permitting thereby septic micrococci to enter its blood, a septic inflammation was at once produced. The other disease I have alluded to in illustration—namely, septic or suppurative endocarditis—we know arises from either the staphylococcus or streptococcus when present in the blood from any accidental cause finding a nidus in an inflamed endocardium or damaged valve, and the chemical product of its growth is then wafted in the blood current to set up mischief in other situations, where, from anatomical causes or lowered vital resistance, the blood and tissues cannot overcome its invasion. The germs of typhoid fever, like all other septic germs, are now regarded as in themselves harmless as long as the tissues with which they are in contact are healthy, else how can we explain the immunity from the disease that exists in healthy individuals who constantly either receive them through food or drink into the alimentary canal, or have them as a normal and constant resident in that channel?

This brings me to the vexed question of the etiology of the disease. If we take it for granted that the bacillus of Eberth is by its infiltration of the glandular tissue of the intestine the cause of all the mischief (and apart from the absence of the inoculation evidence most pathologists are agreed that this is so), what are the conditions that favour or produce its acute infection of those glands? We have first the evidence that this bacillus is found growing most luxuriantly—and we must presume consequently more virulent, and more capable of making a vigorous battle for its existence—in the autumn. But it must find the tissues with which it comes in contact in a weakened condition to get the upper hand in the struggle. Are the intestines at this period of the year in a more weakly condition than at any other, and, if so, from what cause? I think we can answer that question in the affirmative. Most of us are familiar with the gastro-intestinal troubles that are characteristic of the early autumn months, the gastro-intestinal catarrh especially, the catarrhal or autumnal diarrhœa, and the frequency of so-called bilious attacks at this season. How these catarrhs are produced we have a ready explanation in the rapid fall of temperature in the evenings after perhaps a warm mid-day, when the action of the skin is suddenly checked, and no additional precautions as to clothing adopted. All hospital physicians are familiar with the sudden onset of bronchial catarrhs at this season, also from the same cause, and the rapid filling of hospital wards with cases of asthma, emphysema, and fresh broncho-pneumonia in patients the subjects of phthisis during the previous summer and spring. Now let us see if this gastro-enteric catarrh is a usual precursor of enteric fever. Murchison, with that acute power of observation which was characteristic of him, mentions it as a most usual symptom, preceding and accompanying the fever in its early stages; and he further adds that catarrhal diarrhœa was frequently present, preceding the fever, and that it was often difficult to say whether the disease would remain catarrhal diarrhœa or end in enteric fever. Now it seems to me that this catarrh, in addition to being brought about by atmospheric changes or food, may be produced also from the absorption of the chemical products of the typhoid bacilli growing on the intestinal contents, when present in large numbers, in either food or drink containing them; and that this ptomaine or toxine was only the weapon they used, as Professor Burdon-Sanderson expresses it, in their struggle for existence, to weaken the vital resistance of the tissues with which they were in contact, and make it fall an easy prey. Why, however, should the glandular tissue be the first overcome in this struggle? The reason seems to me obvious, looking at it from a pathological point of view. Adenoid tissue is endowed with a very poor vitality, and very little power of resistance, or of repair, when infiltrated or choked from any cause. We see this when it is attacked by a similar bacillus, the tubercular one, whose life history and the readiness with which it infiltrates and destroys glandular structures being somewhat similar to the typhoid one in many ways. The epithelial shedding and proliferation of the mucous membrane which take place must also weaken the defences against the bacillary invasion. The bacilli find the glandular tissue in a condition of derangement from the effects of this catarrh, and it becomes the centre of their habitation. That this invasion is sudden and followed by rapid changes in the glands there can be no doubt, Murchison having found infiltration and swelling of the glands in the case of a patient dying on the second day of the disease, and other observers bear similar testimony. The entire process in connexion with the gland so far as the typhoid bacillus is concerned, from the time of invasion to death or disablement of the gland, is over in fourteen days—the normal time of enteric fever from a pathological point of view. After this period, however, a new set of enemies appear on the scene in the shape of the suppurative micrococci, which, forming colonies on the injured or necrotic tissues around the glands, begin to generate their peculiar toxines, producing the hectic character of the symptoms and temperature with which we are all familiar after the first fortnight of the disease; so that we must regard enteric fever as the result of the growth in the intestines of two sets of micrococci. The so-called typhoid bacilli producing the symptoms during the first fortnight, and the suppurative micrococci producing the characteristic symptoms of its further stages. That other micrococci, as well as these latter, occasionally infect the patient from the intestinal canal there can be no doubt, and I have at present under my care in the Mater Misericordiæ Hospital a patient with a well-marked attack of erysipelas of the face in the fourth week of his enteric fever.

If recent bacteriological work has enabled us to grasp these facts with regard to the disease, we may ask ourselves what practical deductions can we draw from them so as to enable us to treat it. Looking at the disease as primarily a catarrhal one of the intestines, and secondarily as one of septic poisoning, our treatment resolves itself into suitable diet and antiseptics. We know already how all-important is the treatment of enteric fever by bland and unirritating diet, and such as will be mainly absorbed by the stomach and duodenum, leaving little to be dealt with by the lower part of the small intestine. The medicinal treatment of typhoid fever by antiseptics is now receiving that amount of attention which our more perfect knowledge of its bacteriological origin would suggest, and we see occasionally in the medical journals glowing accounts of the success of this method of treatment in the hands of some; while others confess it has not realised their expectations. As far as I am concerned, I have used this method of treatment for several years in both hospital and private practice, and have every reason to be satisfied with the results. I do not profess to believe that it will abort a case of typhoid fever when the characteristic fever has begun, but I do assert that it will prevent in the majority of cases the septicæmia—for it is nothing but septicæmia—which we have to deal with after the second week of the fever is passed. The typhoid bacillus has by this time done its work, so far as the intestinal glands are concerned, and hereafter we have only saprophytic bacteria and their effects to deal with. The characteristic hectic type of temperature during the third and subsequent weeks of enteric fever, such as we have in connexion with suppurating cavities in the lungs or elsewhere, shows this to be the case. In seeking for a suitable antiseptic for this purpose we must choose one which will fulfil the following objects. It must first exercise its effects in the intestinal canal, and not in the stomach. Its action must be thorough, antisepticising not alone the contents of the bowel, but it must permeate the intestinal wall as well, where septic micrococci may have already established themselves, and even enter the blood. To fulfil these conditions the form of antiseptic must be, in my opinion, a gaseous one. We know how readily the intestines absorb gases and pass them into the blood. The antiseptic I am in the habit of using is chlorine in an alkaline solution, as in this form it mingles best with the contents of the intestines, which in enteric fever exhibit a strongly alkaline reaction. This treatment is not original, as Murchison, who expresses himself in general as dissatisfied with antiseptics, speaks favourably of chlorine, and regarded it as an admirable method of treatment. He administered it in an acid solution, which in my experience is not so satisfactory. That this method of treatment produces a fall in the temperature and makes the type of the disease milder there can be no doubt, and in over a fourth of the cases when begun early brings the febrile process to an end about the fourteenth or sixteenth day. Murchison, in his careful statistics, found only seven cases out of 200 to terminate on the fourteenth day by the ordinary method of treatment, so the cessation of the fever by this method of treatment in such a large percentage must be more than a mere coincidence. I do not claim for it that it is the best form of intestinal antiseptic, as

Digitized by Google

more extended experience may enable me to procure a more beneficial one, and I hope on some future occasion to bring before the profession the results of my experiments on this subject in conjunction with our bacteriologist at the Mater Misericordiæ Hospital. I have not in these notes entered the broader field of etiological theories by trying to explain how enteric fever arises through the medium of sewers, or sewer air, or why it is more prevalent among the wealthier classes than the poor, or whether it can arise as a miasma-producing infection through the air. These are matters that I did not intend should enter into the scope of my paper, as I have been content to regard the disease from the bacillary point of view alone, and to see in it sufficient explanation of all the group of phenomena which we call typhoid or enteric fever.

Dublin.

ATTEMPTED LITHOTRITY IN A BOY; SUPRA-PUBIC LITHOTOMY.

By W. T. CLEGG,

SENIOR ASSISTANT SURGEON TO THE LIVERPOOL HOSPITAL FOR SKIN DISEASES, ETC.

R. P——, aged ten, but small for his age, was sent to me, suffering from stone in the bladder, in October, 1891. When seven weeks old the patient had retention of urine, which required catheterisation, and he has had urinary trouble more or less ever since. He walks bent forwards and cautiously. He has retracted testicles, a long foreskin, and a prolapsed rectum. His clothing has a urinous odour. The urine is fetid. On Oct. 7th I attempted to pass a No. 10 Weiss completely fenestrated lithotrite, to ascertain the size of the urethra and of the calculus. The meatus was freely incised, but it would not pass. I then passed a No. 6 Weiss fenestrated lithotrite, which was gripped by the urethra all along, and a large calculus was discovered. Although under chloroform, violent spasmodic straining, amounting to emprosthotonus, even involving the sterno-mastoids, accompanied every movement of the instruments. On Oct. 8th the boy was placed thoroughly under the influence of chloroform by Dr. Stevenson. Dr. Tisdall assisted me, and Drs. Barnes, German, and Price, dropping in as the operation proceeded, were also kind enough to help in various ways. About two ounces of boiled water were injected into the bladder, and a No. 8 Weiss fenestrated lithotrite was passed carefully, but with some force, especially when passing the triangular ligament. The instrument was such a tight fit for the urethra that when moved about the penis moved with it, and this greatly hampered me. The stone would not fall into the jaws of the instrument. I soon found out that it retained a position on the left side of the bladder, and was always to be found there. The only manœuvre that would enable me to grip it was with the lithotrite held vertically, its beak just inside the bladder and turned to my right. I seized the stone and carried it towards the centre of the bladder, locked the male blade, and screwed down upon some rather soft outer coating, coming to a stop as the hard stone was reached. I could trust the lithotrite, and so still screwed on with full force, when with a jolt the stone escaped. The length, weight, and shape of the stone and the small jaws of the instrument fully accounted for this. Three times this occurred. The phosphatic material that came away was mixed with offensive mucus; the urethra was small and in a state of spasm; the stone was large and hard, therefore I reluctantly gave up, thinking it more discreet to do supra-pubic lithotomy. We had no rectal bag, nor did I think one necessary. A light chair was inverted on the operating table, and the boy arranged along the back of it. His head only remained on the table, his knees were bent over the spindle joining the two back legs of the chair, and retained in that position by clove-hitch knots. A sponge was thrust into the rectum lest the contracted condition of the recti and bladder should prevent the viscera gravitating freely enough into the arch of the diaphragm to draw the bladder sufficiently out of the pelvis. This proved to be quite unnecessary. I cut down upon and into the bladder and extracted a stone two inches long and one and one-eighth inches broad, weighing 370 grains without the débris. On first putting the finger into the bladder the impression was that the stone lay in a pouch owing to the contraction of the bladder walls around it, but after its removal no pouch remained. The bladder opening was anchored to the opening left in the linea alba so as to shut off the bladder discharge from the neighbouring tissue. On Friday, Oct. 16th, the boy passed urine through the urethra, and about four weeks later the abdominal wound had healed. The boy is now attending school, and there is a wonderful change in his appearance. The anchoring of the bladder to the linea alba has not given rise to any symptoms.

Remarks.—Lithotrity has been for some years a hobby of mine; I am accustomed to handle the weapons; therefore it will be granted, I think, that there was good cause for abandoning the attempt, and this makes the case worth reporting. Strange to say, lithotrity is as yet the rule only with the few; yet it is almost always applicable to old and young, male and female. It is, in my opinion, the safer proceeding where the kidneys are damaged. An elderly gentleman with damaged kidneys was to have been submitted to me for lithotrity. Meanwhile, he was advised to go elsewhere, was cut, and died the same evening. During the past two years two other similar cases have come to my knowledge. Lithotrity could not have met with worse success in these cases. The completely fenestrated lithotrite is the only form required, and numbers 6, 8, 10, A, B, and C, form a series sufficient to meet every requirement. I much prefer the wheel and button action—the Weiss-Thompson form to Bigelow's form of handle. I have used both, and found the bruising of the palm about the same in each; but with the Bigelow pattern the fluted surface of the lock mechanism makes the skin over the ends of the right index finger and thumb very tender when in use for an hour or more. There is more lurching, too, in working this lock. The jamming of the male blade, to which Mr. Cadge refers in his recent lectures, occurred to me on one occasion whilst sliding the male blade backwards and forwards to ascertain whether it was free after withdrawal from the bladder. I sent it up in its jammed condition to Messrs. Weiss and Son, and they wrote complaining that the instrument had been very badly treated. This remark gave me the clue to the cause. A visitor had taken up the instrument previously to the operation, and had allowed the male blade to fall on the floor. It had bent slightly upwards out of the straight and a small hard fragment of stone had worked under the heel of the male blade preventing any further movement backwards or forwards. The simplest and most convenient of aspirators is the latest Bigelow pattern (Fig. 1950 of Weiss' Catalogue). I do not know of a single fault in it. It has no trap; none is needed. Fragments in the glass bulb are very little affected by the currents passing overhead, and blood or mucus obscures the contents of the glass bulb last. This aspirator can be completely and readily filled from a jug by removing the funnel from the supply-pipe and attaching a foot or two of rubber tubing. Eighteen months ago, in conjunction with Dr. Price, I crushed a stone in the bladder of a seafaring man. I used on that occasion an excellent aspirator, but it required to be immersed in a bucketful of water to fill it, and there was not that quantity of hot water in the house. The filling and replenishing occupied more time in this case than the lithotrity. The patient, a man aged thirty-six, returned to his ship on the third day after the operation, and resumed his occupation without permission and without injury. It is a good plan always to have a second aspirator fitting the catheters. It saves waiting for the refilling. A friend operating on one occasion in private, an unfortunate movement of the patient threw the aspirator on to the floor, smashing the glass bulb. The evacuation had to be finished by plugging the opening which should have been occupied by the glass bulb.

I will conclude by mentioning two points that have impressed themselves upon me. In the first place, the slight symptoms often present with a large calculus; the largest I have met with occurred in a man suffering from strictured urethra, and gave rise to no special symptoms. In the second place, that calculi, however hard, owing to lamination, burst asunder in the jaws of the lithotrite much more readily than might be supposed, and seem to try the instrument less than an equal amount of red sandstone.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE REACTION OF URINE WITH ETHER.

By ANDREW H. SMITH, M.D.,
PROFESSOR OF CLINICAL MEDICINE AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL; PHYSICIAN TO THE PRESBYTERIAN HOSPITAL.

If a specimen of urine, taken promiscuously, be thoroughly agitated in a test-tube with half its bulk of pure sulphuric ether, there will result in most instances an abundant white foam. If now the tube be corked and set aside, this foam rises to the surface and gradually condenses into a greyish gelatinous plug, so firm, it may be, that the tube can be turned upside down without disturbing its contents. In another smaller proportion of cases no foam will result from the agitation, and the ether will immediately separate from the urine and form a clear layer above it. In some instances a second prolonged agitation after the lapse of a few moments will produce the reaction described. In other cases it may be obtained by adding a few drops of acetic acid and shaking the tube again very thoroughly. It will always be noticed that when the reaction occurs the fluid begins to clear first at the bottom, and the clearing progresses upward. When the reaction does not take place the order is reversed, a clear layer of ether appearing first at the top. Pending a thorough chemical investigation as to the nature of the substance thus separated from the urine, I find that the reaction occurs in urine which does not respond to any of the tests for albumen or for peptones. It occurs also in urine from which the phosphates have been removed, and it cannot be obtained with simple solutions of urea or of the urates. It is most abundant in the urine of those who have a good appetite and good digestion, and is usually absent after long fasting, or when the diet is greatly restricted. From these facts it seems probable that it represents an excess of nutritive material taken into the blood and thrown off by the kidneys, and not a product of disassimilation. Albuminous urine responds to the test in the same way and under the same conditions as normal urine, but if the patient is on restricted diet and the urine does not react to the test, it can be made to do so by adding nitric acid and filtering out the resulting precipitate. A portion of the albumen is redissolved by the acid, and at the time so modified that it is acted upon by the ether. This is shown by the fact that if the albumen be removed by heat and filtration before the acid is added, the reaction cannot be produced; but if a drop or two of acid be placed upon the filter, the filtrate immediately responds to the test. The same effect may be produced by acid spontaneously generated in the urine, so that a specimen of albuminous urine which will not show the reaction while fresh may do so after the acid fermentation has progressed for twenty-four or forty-eight hours.

It is possible that the presence of this material in the urine, and its peculiar reaction with ether, may explain some cases of anuria after prolonged etherisation. The ether being eliminated by the kidneys and mixing intimately with the urine in the tubules, affords all the necessary conditions for plugging the latter with gelatinous material, too firm to be displaced, suspension of function necessarily following. Until we know more of the possible reactions of this substance, it will be well to receive with caution the results of some of the more "delicate" tests supposed to detect the presence of minute proportions of albumen.

New York.

TWO CASES, INTERESTING FROM THE WAY IN WHICH DEATH WAS BROUGHT ABOUT.

By H. D. ROLLESTON, M.A., M.D.CANTAB., M.R.C.P.,
PATHOLOGIST TO ST. GEORGE'S HOSPITAL.

CASE 1.—*Suicidal bullet wound; bullet compressing the right internal carotid; cerebral softening; death.*—J. C—— was admitted to St. George's Hospital under Mr. Rouse in an insensible condition with left hemiplegia, death occurring within twelve hours. Twenty-four hours before admission the man had shot himself in the mouth with a pistol. At the post-mortem examination there was no wound of the dura mater, and the sinuses were normal. There were ecchymoses on the under surface of the right frontal lobe. The lenticular and caudate nuclei and the optic thalamus on the right side were in an extreme state of white softening; this softening did not extend to the cortex. The left hemisphere of the cerebrum was normal. On removing the dura mater from the middle fossa there was found to be a fracture at the apex of the right petrous bone. There were some small fragments of bone and a little dry blood-clot. Lying in contact with, compressing but not having perforated, the internal carotid artery was a mass of lead three-eighths of an inch long and a quarter of an inch broad and deep. The bullet then had come to rest on the apex of the petrous bone of the right side, and had compressed the internal carotid artery, thus causing extensive softening of the right cerebral hemisphere and death.

CASE 2. *Sarcoma of the right testis; secondary growths in the lumbar glands; thrombosis of the inferior vena cava; embolism of the right pulmonary artery; sudden death.*—A. D——, a well-nourished man aged twenty-two years, was brought in dead into St. George's Hospital. The following history was obtained from his companion. He had been in Hyde Park, lying down on the grass; on getting up and walking a few yards he fell to the ground with a cry of pain, pressing his hands to the front of his chest; he became "black as jet" in the face, and died very speedily. At the post-mortem examination there was a congenital inguinal hernial sac on the right side which contained omentum, but which had evidently contained some coils of adherent small intestine at some former time. The right testis was enlarged to about three times its normal size, was knobby on the outside, and on section was seen to be occupied by a hæmorrhagic new growth, which microscopically was a sarcoma; the tunica vaginalis was not adherent. The glands around the inferior vena cava were greatly enlarged, from the presence of new growth like that in the testis. These glands infiltrated the wall of the inferior vena cava below the entrance of the right renal vein, and produced an adherent clot which narrowed but did not occlude the lumen of the vessel. Lungs: Left somewhat œdematous; no clot in the left pulmonary artery or its branches; right normal; the right pulmonary artery contained a firmly fixed but not adherent clot, which on section resembled that in the superior vena cava. Brain, heart, and other organs healthy. The points of interest are (1) the early sarcomatous disease of the testis, setting up considerable secondary growths; (2) the production of pulmonary embolism.

PERFORATION OF THE MASTOID FOR MIDDLE-EAR DISEASE.

By ALEX. BLACK, M.B., F.R.C.P. EDIN.,
SURGEON TO THE EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH.

Of the methods employed in opening the mastoid, antrum, and middle ear for disease of these cavities, the most usual are those by means of the hammer and small chisel and gouge, and of the trephine. The objections to the first of these methods seem to be chiefly in the amount of concussion upon the interior structures of the cranium beneath the seat of operation, and in the danger of wounding the lateral sinus in the event of too much force being used, or of a splinter of bone being detached and penetrating it. The other usual method—that of the trephine—seems to have the usual objections of trephining operations—namely, constant adjustment of the cutting edge and the removal of the disc of bone. To obviate these objections it was suggested by Dr. Hunter Mackenzie in several recent cases to use the instruments designed by Mr. Watson, dental surgeon, for the purpose of boring into the antrum of Highmore through the alveolus of the superior maxilla. We acted on this suggestion, and as the results proved eminently satisfactory in all the cases, both as regards the ease and safety with which the operation was performed and the good after results from the free drainage established between the mastoid antrum and middle ear and the external auditory meatus, it occurred to us that the instruments might be found useful by others. They consist in a gimlet with a small point, and the diameter for children of the screw of about one-sixth of an

Digitized by Google

inch. This is cautiously inserted into the bare bone, and slowly turned by the hand till the cavity is reached. When this occurs, use is made of a cone-shaped burr, in order to enlarge the opening. These instruments can be made of any size, so that any dimension of opening can be made. After an opening of sufficient size has been made, and a free drainage established through the external auditory meatus, a metal wire twisted into a close spiral is inserted into the bone, and kept till the discharge has almost disappeared. During and after the operation the parts are constantly irrigated with an antiseptic solution. In none of the patients was there any rise of temperature or untoward result after the operation. All the cases were instances of chronic suppurative inflammation of the middle ear with mastoid abscess, and of some months' duration. The ease and safety with which the operation is performed, and the good afterwards resulting, seem to us to widen the indication for its performance. The instruments are made by Mr. Young, Forest-road, Edinburgh.

Edinburgh.

CASE OF PUERPERAL ECLAMPSIA.

By JAMES GILROY, M.B., C.M.

ON March 7th, about 10 P.M., I was called to see Mrs. F——, a patient expecting her confinement about this date. She was over forty years of age, and a primipara. The patient was threatened with abortion in June last, but under opium and careful carrying out of instructions it was averted; and she had gone on, as she thought, perfectly well until three weeks ago, when her feet swelled a great deal, but nothing occurred to make her seek advice. This evening I found great cause for alarm. The patient was seized about 8 P.M. with severe pain in the head, blindness, and delirium. So far as I could elicit, these symptoms came on suddenly. When I arrived she wandered slightly in her talk, but was sufficiently conscious to tell me she had been very ill, but her head now felt greatly relieved, and although she could not see me distinctly she knew me quite well. Her attendants informed me she had two fits in close succession after her husband left to summon me about 8.30 P.M. Examining the pupils, I found them widely dilated and applying a candle closely produced no effect whatever. I examined per vaginam, and found the os a mere chink, totally undilated, and admitting the point of the examining finger very much as a thimble would. I procured a little of her urine, which had been scanty and voided at frequent intervals, and found it loaded with albumen. On heating it became a mass of jelly consistence at once. Her face had all the characteristics of kidney embarrassment, pale, waxy, and puffy eyelids, pulse moderate in fulness and strength, about 76 per minute. I decided to try chloral and bromide of potassium, having found it work well in a previous case where convulsions ensued after delivery. Accordingly I administered twenty grains of chloral hydrate with twenty grains of bromide of potassium, and after waiting some time, and being uncertain as to the advisability of inducing labour, I gave instructions that the patient should receive a similar dose six hours later, after which I would see her again; and in any case, if convulsions threatened or occurred, that I should be called.

I saw her again at 10.30 A.M. on March 8th. The nurse told me she had slept very little or not at all, but had had no more seizures since I left; so that the two she had before I saw her were all that had occurred so far as is known. I did not like the aspect of the patient that day. She was dusky in the face; pulse over 100; breathing rather hurried, approaching dyspnœa. There being every indication therefore of a serious issue, I resolved to induce labour, and with that view passed a gum elastic catheter into the uterus. After waiting about an hour and a half and no contractions occurring, and as the os was quite undilated, I tried cautiously to dilate it. The breathing of the patient discouraged me from using chloroform; and as she had vomited freely during the night I hoped to obtain a moderate degree of dilatation, and then administer a little chloroform, pass the instruments, and deliver. I had the aid of Dr. W. B. Crichton, which is a division of the anxiety one naturally feels in these terrible circumstances. I was proceeding, as I thought, fairly, and the os yielding moderately well, when, with lightning swiftness never to be forgotten, the patient, who all the morning had been conscious and cheerful although now and again slightly rambling in her talk, but greatly better than on the previous evening, stopped breathing. There were no clonic or tonic contractions visible. The lips did not alter much, if at all, but a bluish tinge was seen round the mouth. We tried to restore her by artificial respiration, and once or twice clung to the hope of being successful as she made one or two spasmodic efforts at breathing, but at length it became too apparent all was over with her. We immediately thought of the child, but the friends would not allow post-mortem operation. The case demonstrates the difficulties of deciding upon treatment, and the risks to which any line of treament is open. I did not deem the case one for bleeding.

ST. GEORGE'S HOSPITAL.

CASE OF COMPOUND DISLOCATION, WITH VERSION, OF THE ASTRAGALUS; REMOVAL OF THE BONE; RECOVERY.

(Under the care of Mr. PICK.)

THE following case of dislocation of the astragalus from all its articulations, with version of the bone, seems worthy of being placed on record. As will be seen in the account of the case, the bone was so nearly severed from all its connexions that it required only the division of two small bands of ligamentous tissue to completely free it from all its attachments, and a very little extra force would have caused it to project from the wound and fall to the ground entirely detached from the foot. In this respect it nearly resembles the classical case referred to by Norris,[1] where the bone was found lying on the ground some distance from the patient. The account that the man was able to give of the accident did not show very clearly the exact mode of its causation; but, as Mr. Barwell has pointed out, it would appear that it is produced by violent twists of the foot when it is at right angles to the leg, and in a position neither of extreme flexion nor extension. For if the foot is acutely flexed, at the moment the force is applied dislocation backwards results; and, on the other hand, if the foot is hyper-extended, the result is dislocation forwards. Mr. Barwell has also very justly pointed out that there must be a certain relationship of strength between the ligaments of the ankle and those connecting the astragalus and os calcis. For if the latter be weak in proportion to the former, subastragaloid dislocation would alone occur, the ligaments of the ankle-joint, on account of their greater proportional strength, escaping rupture, and thus maintaining the ankle-joint intact. On the other hand, if the ligaments of the ankle-joint were the weaker, they would give way, and dislocation at this articulation alone result, the astragalo-calcanean joint escaping injury. We are indebted to Mr. L. Moysey, dresser of the case, for the following notes.

T. S——, painter, aged forty-five, was admitted into St. George's Hospital on Nov. 7th, 1891. He stated that shortly before admission, whilst standing on a scaffold painting a ceiling, the scaffold gave way, and he fell to the ground. In his fall his foot caught the end of a plank and twisted it. He states that he has always enjoyed good health, and has never had any illness, except ague, thirty years ago, in the West Indies. He has had no specific disease, and has always been a moderate drinker. His family history was good. When admitted he was faint and collapsed, with a small, weak, and running pulse and a pale face. The anterior part of the foot was turned inwards at the mid-tarsal joint, so that it was at about a right angle with the axis of the leg. On the outer side of the foot was a wound, extending from the front of the ankle-joint, just ex-

[1] American Journal of the Medical Sciences, 1837, p. 383. Case under the care of Dr. Barton, fatal from gangrene of limb and tetanus.

Digitized by Google

ternal to the tendon of the extensor longus digitorum, obliquely downwards and outwards to just below and in front of the external malleolus; through this was protruding the head and neck of the astragalus. This bone was, therefore, rotated on a vertical axis drawn through the centre of the bone, so that the semilunar facet for the internal malleolus was directed forwards and the triangular facet for the external malleolus backwards, and the long axis of the superior saddle-shaped articular surface was directed from before backwards, instead of in a transverse direction. The bone was held in this position by a part of the external lateral ligament and a band of fibrous tissue on the inner side of the bone. These were divided, and then the bone was easily withdrawn with the fingers. The astragalus was intact with the exception of a slight graze on the head of the bone. There was no fracture of any other bone, and but slight bruising of the soft parts. The cavity left by the removal of the bone was thoroughly irrigated with a solution of corrosive sublimate, a drainage-tube inserted, and the wound closed and dressed with double cyanide gauze. The limb was placed on a back splint with a foot piece. The subsequent progress of the case requires no comment. There was a little quiet suppuration, which somewhat retarded recovery, but otherwise he went on well, and was eventually discharged with a sound and useful limb.

DEVONSHIRE HOSPITAL, BUXTON.

FRACTURE OF THE ANTERIOR INFERIOR SPINE OF THE ILIUM BY MUSCULAR ACTION.

(Under the care of Mr. SHIPTON.)

THE case which Mr. Gibson (to whom we are indebted for the notes of the case) describes is a most unusual one, and our works on surgery, general or special, contain no references to such an injury. Fracture of the anterior superior spine as a consequence of direct injury is not uncommon in our accident wards; and there are at least five recorded examples of separation of that process by muscular action. Fracture involving the anterior inferior spine, except as the consequence of gunshot injury or a severe crush of the ilium, is apparently unknown.

E. M——, aged thirty-five, bricklayer's labourer, was admitted into this hospital on Dec. 12th, having fallen from a scaffold sixty feet high. He was found to be in a semi-conscious condition. The right leg was more everted than the left one, the front part of the right thigh had lost its rounded outline and was a good deal flatter than the other. There was no fracture of any limb. A catheter was passed without difficulty and four ounces of clear urine drawn off. On grasping the ilia, no mobility or crepitus could be made out. On carefully examining the pelvis, a piece of the anterior edge of the right ilium, about one inch in length and three-quarters of an inch in breadth, comprising the anterior inferior spine with the origin of the short head of the rectus, was found to be detached from the ilium to the extent of about a quarter of an inch, and could be easily moved between the fingers. There was no redness or ecchymosis on the skin over the part, but a slight discolouration appeared three days later simultaneously with very marked ecchymosis around both eyes. The rectus was relaxed, and later on, when the patient had recovered consciousness, he was asked to flex the right thigh, which he did with difficulty and pain—situated at the seat of fracture,—but only raising the thigh a few inches from the bed; and the anterior inferior spine was found to be still further separated from the rest of the bone. No other injury was found. On obtaining the history of the accident from the patient, it was ascertained that whilst carrying a hod full of bricks over his left shoulder his foot slipped, and to prevent the bricks falling on him he threw the hod backwards, falling on "all-fours" into a quantity of soft shale, sixty feet below. This statement was corroborated by a fellow-workman who saw the accident. The patient made an uninterrupted recovery, a good deal of callus being thrown out around the fracture.

Remarks by Mr. GIBSON.—The case is of interest, as the fracture appears to have been caused by muscular action. I have come to this conclusion on consideration of the following facts: (1) The history of the case shows that the right rectus must have been suddenly and forcibly brought into action when the patient threw the hod over his left shoulder, so as to help to steady the pelvis, and so prevent him from falling backwards. The long head of the rectus was probably ruptured simultaneously. He fell on his hands and knees into a quantity of soft shale, which partially buried him, and therefore it is improbable that the injury was caused by the fall. 2. The absence of redness or bruising until the third day, when a little discolouration appeared over the part simultaneously with considerable ecchymosis around both eyes. 3. The anterior inferior spine is well protected from direct violence on all sides by muscle, and on the outer side, where it is most accessible to injury, it is shielded by the great trochanter as well. 4. Absence of evidence of any further fracture of the pelvis. Having never heard of a similar fracture by muscular action I venture to record the case.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Operative Treatment of Congenital Dislocation of the Hip.

AN ordinary meeting was held on March 22nd, the President, Mr. Timothy Holmes, in the chair.

Mr. BARWELL communicated a paper on the Operative Treatment of Congenital Dislocation of the Hip. The condition thus called was, as many anatomical investigations had shown, absence, more or less complete, of the acetabulum, usually combined with a certain truncation of the head of the femur. The well-known signs of the deformity were merely mentioned, and a symptom not hitherto noticed was described and illustrated by a sketch rapidly taken from a patient—namely, when she bowed forwards with straight knees till the back of the pelvis was nearly horizontal the great trochanters, or the trochanter in unilateral cases, projected upwards and outwards from the ossa innominata, and lay in some cases actually higher than those bones. Stress also was laid on a jolt which occurred when the limb was drawn down far enough to bring the head of the bone into its normal situation. Two prevalent methods of treatment were described: the one by division of the rotators and capsular muscles, originating with M. Guérin, and recommended by Mr. Brodhurst; the other by long-continued recumbency with extension, inaugurated by M. Pravaz, followed in America by Dr. Buckminster Brown, and in England by Mr. Adams. According to the last-named the recumbency must occupy two or two years and a half, and be followed by a year and a half of instrumental treatment and of go-cart and crutches. It must begin, in order to have chance of success, in infancy, or very little beyond that period. The writer stated that this deterrent period of treatment might be very much shortened, the chances of success greatly increased, and cases seen at a later age might be cured by the division of certain muscles. But he contended that the rotator and capsular muscles were valuable aids in keeping the head of the femur *in situ*, and must be left intact; while the muscles which ran from the pelvis to the femur, in a direction almost parallel to the axis of the latter bone, being those which, in the absence of an acetabulum, propelled its head upward on to the dorsum ilii, were those which should be divided. Indeed, the extension which Pravaz and his followers carried out for such lengthened periods could only avail by counteracting this action of those muscles, which might be much more surely, rapidly, and as safely overcome by division. Three cases were given, the oldest beginning treatment at eleven years of age, in which the author divided the adductors &c., and allowed the patients to get up in a few weeks, and which were completely successful. A letter from the first patient was given, describing her activity and power. The author showed one of the younger patients.

Mr. BRODHURST said that in one of the cases, though the result seemed to be exceptionally good, yet there appeared to be some doubt whether it had ever been one of congenital dislocation; the femur also in that instance was short, and he did not remember ever to have seen a shortened femur in association with this malady. The author had made a mistake with regard to Guérin's opera-

Digitized by Google

tion; the latter only divided the tensor vaginæ femoris, the gluteus medius, and the anterior part of the gluteus maximus; a weight of five kilogrammes had then been attached to keep the bone in position. In 1865 he operated on a case of one-sided congenital dislocation of the femur. He divided the gluteus medius, the trochanteric attachment of the gluteus maximus, the psoas and iliacus, the gemelli, and the obturators; he then drew the bone down, and found that it remained in that position. It was then fixed on a splint for two months, after which all the movements of the limb could be effected perfectly. At the end of twelve months no apparatus was used, and there was no deformity at all. In other cases, where the age was more advanced, he had divided the abductor longus, but he had never resorted to division of the rectus femoris.

Mr. NOBLE SMITH had treated these cases at first with a raised shoe, and with this in many the deformity had not increased, though in some this had taken place. The cases treated by Pravaz's method had given interesting results, but it necessitated very prolonged rest and expensive instruments. In one case in which he had adopted the rest treatment without the instruments he got a good result. He preferred to apply a Liston's long splint with a perineal band, which was better than extension by weights, for the latter continued to pull down the limb beyond what might be required. He would advocate the treatment by prolonged rest in all cases except those in which there was contracture of the muscles.

Mr. MUIRHEAD LITTLE referred to a case under his care in which the patient was reclining on a long couch with cord extension. After a few weeks there was no difficulty in overcoming muscular action and keeping the trochanters in position. After nine months of this treatment it was found that the trochanters remained in position when the weights were removed, and he hoped for a good result.

Mr. GODLEE thought that in such a debate a word should be said regarding Professor König's operation of manufacturing a new acetabulum. He made a curved incision above the trochanter, and then with a chisel reflected a portion of the ilium downwards towards the capsule. One of the cases he had so treated died of diphtheria, and he found at the necropsy, performed some time later, that a very good acetabulum had been formed.

Mr. BARKER inquired what occurred to the dorsum ilii when the femur had been held in position against it for some time. He doubted if a proper acetabulum could be formed in the absence of irritation or movement.

Mr. BOWLBY asked if it were considered that this operation was necessary in all cases, many of which differed so much from each other. In some, where the head of the bone was forward, the patients walked well, but where the bone was displaced backwards there was more limping and greater sliding of the bone on the dorsum ilii. At a time when a child began to walk it was necessarily unstable in its gait, but later it had educated its muscles, and these facts should be taken into consideration in judging of the results of treatment at this early age. In the two younger cases that Mr. Barwell had operated on the procedure had been carried out at such an early age that it was quite impossible to guess what would have happened if they had been left alone.

Mr. HOLMES remembered the case which Mr. Brodhurst had related. The division of muscles which had been recommended was put forward as accessory to other treatment, with a view to hasten it, and he supported the view that a judicious subcutaneous section of muscles brought about a more rapid result than could be obtained by rest alone. Mr. Barwell, in addition, attempted to produce something in the way of an acetabulum after the manner of König. In spite of Mr. Bowlby's criticism, he held that in the greater number of cases of congenital dislocation the deformity might go on increasing until the patient could scarcely walk at all, and for these operation was advantageous. He added that a valuable appendix to the paper would be drawings or photographs of the cases before operation was undertaken.

Mr. BARWELL, in reply, said that the only object of his method was to expedite treatment, which was often otherwise most irksome. He had endeavoured to make a lip of bone above the femur to form some sort of resistance to the upward gliding of that bone. Many of these cases were not so easily treated as some of his critics seemed to think. He had not practised König's operation, which he considered to be too severe a measure. His first case was eleven years and a half old when he operated. He was not convinced of the advantage of dividing the anterior fibres of the gluteus maximus and the obturators.

CLINICAL SOCIETY OF LONDON.

Nerve grafting.—Abdominal Section in cases of Ruptured Spleen and Liver—Mediastinal and Pulmonary Carcinoma associated with Retraction of Chest Wall—Modes in which a Strangulated Loop of Bowel reacts to the Constricting Medium.

AN ordinary meeting of this Society was held on March 11th, the President, Sir Dyce Duckworth, in the chair.

Mr. DAMER HARRISSON read a paper on a case of Nerve-grafting. After recalling the excellent results which followed close apposition of the ends of divided nerves the author observed that the only satisfactory method of dealing with nerves the ends of which were too far apart to admit of their being sutured was by nerve-grafting. He referred in detail to the history of eight cases in which this operation had been performed at home and abroad, and then proceeded to narrate the following case under his own observation. A lad, aged thirteen, was admitted into the Liverpool Northern Hospital on June 4th, 1891, with the following history:—Eleven weeks before a glass cut of the front of the right wrist divided *inter alia* the median nerve and all the flexor tendons except the flexor carpi ulnaris. On admission the fingers were found to be immovably fixed in the flexed position, paralysis of both motion and sensation being complete, corresponding to the median nerve. Trophic changes were also present, the hand being blue and cold, the skin glossy, and the short muscles of the thumb much atrophied. Mr. Harrisson explored the site of the original injury and found the flexor tendons matted together and nearly two inches of the nerve had been destroyed, leaving a gap between the ends. After dealing with the tendons the nerve ends were freshened, thus increasing the separation to two inches, and a graft two inches and a quarter in length, taken from the sciatic nerve of a recently killed kitten, was fixed in a position by one fine catgut suture, at each end passing through the substance of the nerve. The limb was then put in a splint, with the hand flexed and the fingers straight. The wound healed by first intention. Sensibility began to return in the palm of the hand and over the first phalanx of the thumb at the end of forty-eight hours, and by the third day had extended to the first phalanges of the index and middle fingers and the terminal phalanx of the thumb, and eventually over the middle phalanges of the index and middle fingers. Sensation had not returned in the tips of the fingers. There was also transference of sensation, impressions from the first phalanx of the index finger being referred to the corresponding area of the middle finger. At the end of three months the nutrition of the hand also showed great improvement. Motion showed no signs of returning until the end of five months, when slight voluntary movement was observed in the short muscles of the thumb. Though still feeble, these movements were improving, and within the last three months the patient had been enabled to oppose the thumb to the index finger. The flexion of the fingers upon the palm was not perfect, doubtless on account of the destruction of the tendon of the flexor sublimis digitorum. In another case of the same kind an operation had still more recently been performed by Mr. Mitchell Banks of Liverpool upon the ulnar nerve at the elbow after excision of a neuromatous tumour, four inches being grafted from the sciatic nerve of a dog. Sensation was stated by the patient to have returned within thirty-six hours. Of the ten cases quoted by him three had been perfectly successful, six partially successful, only one proving a failure. He attributed the difference in the success attending primary and secondary grafting to the trophic disturbances which were present when grafting was resorted to as a secondary operation. Restoration of function took place readily enough after long periods of time in respect of sensory nerves, but the degeneration which took place forthwith in the distal portion of motor nerves rendered repair slow and the return of function very gradual.—The PRESIDENT asked the author if he could state what kind of graft formed the best material for a conducting medium.—Dr. SAVILL inquired what limit could be left between the divided ends of a nerve so that it could undertake its own repair without recourse to the introduction of

Digitized by Google

extraneous material. He referred to a case in which he had excised half an inch of the right median nerve in a case of tetanus; afterwards neuromatous enlargements developed on the divided ends, necessitating further removal, so that a gap an inch and a half wide was left. He brought the ends together without the intervention of a graft, and, though recovery was much delayed, at the end of a year and a half or two years there was perfect restoration of all the functions of the limb.—Mr. HARRISSON, in reply, said that all the materials which had been hitherto employed seemed to be nearly equally successful. The earlier return of sensory functions was to be expected, because the sensory fibres in the distal portion did not degenerate. There was no evidence at present to show the rate at which the motor fibres grew downwards; in Dr. Savill's case it seemed to have taken at least eighteen months.

Mr. PAGE related three cases in which Abdominal Section had been performed for Ruptured Viscera, in one instance the spleen, and in two the liver, being the organs injured. These were cases of abdominal injury without external wound, in which general peritonitis began within a few hours of the accidents, and was due to the presence of large quantities of extravasated blood in the peritoneal cavity. The abdomen was opened in the case of ruptured spleen forty-six hours after the accident, and the complete washing out of blood from the peritoneum gave marked relief, lessened the evidences of peritonitis, and seemed to come very near indeed to saving the boy's life. The injury in the first case of ruptured liver was more severe, several ribs being broken, but here also the peritonitis was unquestionably reduced by peritoneal flushing twenty-seven hours after the accident. In the second case of ruptured liver the injury was complicated by slight laceration of one kidney, and the amount of hæmorrhage had been enormous. Operation gave no relief twenty-nine hours after the accident. Notwithstanding the results in these three cases the object of the writer in recording them was again to urge the advisability of early exploration, and especially whenever peritonitis followed an abdominal injury without external wound. The propriety of such a step had been well established in the case of ruptured intestine, but the surgeon might have to do with a lesion of one of the viscera, in itself of comparatively small moment. The real source of danger in such cases lay in the stagnant blood in the peritoneal cavity, and in abdominal exploration and peritoneal flushing there were the means of averting death from the general peritonitis which was almost certain to ensue.—Mr. LANE referred to some cases of uncomplicated rupture of the spleen which had come under his care. The first was a lad aged fifteen, who, when driving a doctor's brougham, fell off and was struck by the pole. Mr. Lane opened the abdomen at once, found the spleen pulpy, and removed it. A large quantity of blood was evacuated, and the boy lived for five hours after the operation. The second case was that of a child aged four, who had also received a blow over the abdomen from the pole of a carriage. The abdomen was opened as soon as possible, and the spleen, which was completely broken up, was removed. The patient survived for about five hours. In a third case in which the speaker had performed abdominal section he found a large rent in the liver. He could control the hæmorrhage from this by grasping the organ in his hand, but he found it impossible to suture the rent, as one side of it had been driven inwards by the traumatism. He therefore plugged the wound in the organ with several yards of iodoform gauze, and then, the patient having lost much blood, transfusion of saline fluid was resorted to, the basilic vein being selected as the site of introduction. But it was found that immediately the fluid was thrown into the vein the bleeding at the liver recommenced, so it had to be abandoned, and the patient died. He held that wherever there was evidence of damage to viscera the abdomen should be at once opened.—Dr. HANDFIELD JONES related the case of a girl who was suddenly seized with signs of peritoneal hæmorrhage. She died five days later, and at the necropsy forty-two ounces of blood-clot were found in the peritoneal cavity, yet there were no signs of peritonitis. In the right tube was a ruptured ectopic gestation of about six weeks' growth. Another similar case was recorded in the *Centralblat. f. Gynec.*, 1891, in which, on operation three days after the rupture, the peritoneum was found full of blood, and yet there was no trace of inflammation. In another case which had been under his care a tubal gestation of three months and a half ruptured first into the layers of the broad ligament, and afterwards into the general peritoneal cavity. Thirty hours afterwards acute peritonitis developed, but then liquor amnii as well as blood had been extravasated. He thought that it was the admixture of these impure products which excited the inflammation.—Dr. VOELCKER referred to the case of a child aged eight who was recently admitted into the Middlesex Hospital after having been run over by a cart. There was no external wound, but the symptoms were those of an intra-peritoneal extravasation of blood. The child lived for five days, and at the necropsy four ounces and a half of blood were found in the peritoneum. There was a laceration on the posterior border of the right hepatic lobe, which was partly sealed by blood-clot. The only evidence of peritonitis was an extremely small flake of lymph on the upper surface of the liver, the general peritoneal sac being unaffected.—Mr. BOWLBY had not observed peritonitis to arise in connexion with rupture of the spleen, but he had frequently seen it in association with rupture of the liver, and he attributed it then to the coincident extravasation of bile. It should be remembered that the injury which caused the rupture of the spleen might also so damage the peritoneum as to excite inflammation in that structure. He felt sure that the mere presence of blood in the peritoneal cavity did not inevitably or even usually set up peritonitis. If every case of suspected rupture of viscera were operated on, more patients would be killed than cured. He did not see what surgical measure could benefit in a case of rupture of the liver.—Mr. SILCOCK said that a child was brought into St. Mary's Hospital after a very violent injury to the abdomen. For some time all went well, and then marked peritonitis set in. He found, on examination, that the rectum was full, and so the bowel was emptied, and iodine rectal injections given. A few hours after the first injection a large quantity of fæces came away, and the temperature sank to normal, though abdominal distension and tenderness remained for some time. The severity of the injury was proved by the fact that a week after the accident the whole surface of the abdomen turned perfectly black from extravasated blood. In this case there was a large extravasation into the peritoneum, and the timely removal of the septic fæcal material in the bowel prevented the migration of microbes into the exuded material.—Mr. HERBERT ALLINGHAM said that he had been recently called to the Great Northern Hospital to see a child who had been run over by a heavy waggon. The symptoms induced him to open the abdomen, and he found the peritoneum full of blood. Having washed out the cavity he closed the wound and inserted a drainage-tube. The child died four days later of peritonitis; at the necropsy there was found a rupture of the posterior surface of the liver, and it was around this that the peritonitis had commenced.—Mr. PAGE, in reply, said that the weight of evidence seemed to be against the idea that the blood of itself could set up peritonitis. But it should be borne in mind that the condition usually present was that of a large collection of blood, which was only separated by the thinnest membrane from the septic intestinal canal; this of itself justified the washing out of the blood from the serous sac.

Dr. PERCY KIDD related a case of Mediastinal and Pulmonary Carcinoma, associated with Retraction of the Chest Wall. The patient, a butcher aged fifty-two, had suffered from cough, expectoration, dyspnœa, and wasting for three months. On admission there was retraction of the left side in front, with dulness over the whole lung, most marked at the upper lobe. The inspiratory murmur was very feeble throughout, expiration being faint and blowing at the apex. On the right side the physical signs were normal. The heart was not displaced. The temperature maintained a remittent character throughout, ranging from 101° at night to 99° in the morning. A troublesome cough with copious expectoration, which the patient voided with difficulty, and dyspnœa were the chief symptoms. The sputum was repeatedly examined for tubercle bacilli, with a negative result. Death occurred from exhaustion about eight weeks after admission. The case was regarded as one of chronic phthisis, with thickening and adhesions of the pleura. The necropsy disclosed a large carcinomatous growth in the fork of the trachea, extending into and infiltrating the upper lobe of the left lung, which was firmly adherent to the ribs, the lower lobe was partially collapsed, and the bronchi were dilated and filled out with pus. The whole was much reduced in size. There was no growth in the right lung, which was large, and contrasted strongly with the left. The left main bronchus was moderately narrowed from infiltration of its mucous lining. In conclusion, the exceptional occurrence of contraction and the diagnosis of such

Digitized by Google

cases were briefly considered.—The PRESIDENT asked if there was any œdema of the chest wall or of the upper extremity, conditions which were frequently associated with malignant disease of the lung.—Dr. KIDD, in reply, said that there was no œdema, nor were the veins distended. Though the bronchus was narrowed, yet it seemed that the growth was more a pulmonary than a mediastinal one, and the retraction was probably produced by the simultaneous obstruction of a great number of the smaller bronchi.

Mr. ARBUTHNOT LANE read notes of a series of cases illustrating the Modes in which a Strangulated Loop of Bowel reacted to the Constricting Medium, and he illustrated it by two cases of strangulated hernia, on which he had recently operated. Both these cases were remarkable for the extreme sharpness of the constricting edge. In one, a congenital hernia occurring in adult life, the loop of bowel had passed, along with a piece of omentum, through a small aperture in a diaphragm-like structure. The portion of bowel in the sac was not much congested, and appeared as if it would at once perform its functions satisfactorily on being returned into the abdominal cavity. The distal portion of the loop was shielded from the very sharp constricting margin by the omentum, but more than three-quarters of the circumference of the proximal portion of the gut had been subject to its pressure. This piece of the bowel had by a process of ulceration been deprived of all but its peritoneal coat for a breadth of nearly an eighth of an inch. This coat appeared very thin and fragile, but was not perforated. Mr. Lane invaginated the damaged portion of the circumference of the bowel into that beyond and retained it with sutures. The man recovered and leads an active life. The second case was one of reduction *en masse*, in which the contricting medium was precisely similar in character to that in the preceding case, but in it both proximal and distal ends of the loop were so deeply ulcerated as to leave only the peritoneal coat along the line of constriction, and though there was no obvious perforation, the fluid in the sac and that in the abdominal cavity in the vicinity of the hernia emitted a strong odour of fæces. The loop was excised, and the ends of the bowel approximated by Senn's method. Symptoms of peritonitis, which were only local before the operation, soon became general, and death ensued on the following day. In this, as in the first case, the loop of bowel showed no material change, except at the point of constriction. It would have been impossible to have performed the operation at all owing to the very enfeebled state of the patient, but for the free intravenous injection of saline solution. With these two cases he contrasted the condition of bowel seen in strangulated hernia, when the constricting medium is broad and produces no local distinctive change in the gut. In such, the condition of the strangulated loop stimulates that resulting from the experimental ligature of a loop of bowel by a piece of broad tape or gauze, the bowel becoming intensely congested, thick, leathery, inelastic, and, for a longer or shorter time after the constriction has been removed, functionless. If it be subjected to the influence of the constriction for a sufficiently long time, gangrene took place at the convexity of the loop, commencing at a point most distant from the constriction. He pointed out that between these two extremes any number of intermediate conditions and combinations occurred, and he indicated their importance surgically. The freedom of the bowel from congestion in the two cases described he explained in this manner: When the loop first became strangulated it probably soon became more or less congested, but the very sharp constricting margin produced rapid destruction of the soft mucous and muscular coats of the bowel by its pressure, and their consequent disappearance enabled the veins which were orginally constricted to dilate, and to occupy the space filled originally by these bulky coats, so the back flow of blood from the bowel was carried on sactisfactorily, the loop recovering its normal appearance more or less completely and rapidly.

MEDICAL SOCIETY OF LONDON.

Operation on Injured Median Nerve.—Acute Epiphysitis of Humerus.—Senile Cutaneous Tuberculosis.—Nephrectomy.—Compound Fracture of Skull treated by Trephining and Replacement of Bone.—Partial Removal of Clavicle for Necrosis.—Spina Bifida Occulta.

A CLINICAL MEETING took place on March 21st, Professor William Rose, Vice-President, in the chair.

Mr. PICKERING PICK showed a patient in whom there had been Accidental Division of the Median Nerve, and in whom operation resulted in restoration of function. In January, 1889, a girl, aged five, was running along the street when she fell, a bottle which she was carrying was broken, and one of the fragments cut her arm. The medical man who attended her sutured the tendons, but he failed to find the distal end of the median nerve; he therefore closed the wound without bringing the severed ends of that structure together. In April, 1891, the case came under Mr. Pick's care. He made an incision, easily found the upper bulbous end of the median nerve, but he had great difficulty in discovering the attenuated lower end. It was separated by so great a distance from the upper portion that even after stretching the latter he could not bring them within an inch of each other. But he found lying beside the upper cut end some organising inflammatory material, and he dissected this from the side of the nerve, leaving it still attached to the lower end of the upper fragment, and turned it down and sutured it to the lower end of the nerve. By the eleventh day the wound had healed. On her return in October last sensation was found fairly good in the digits supplied by the nerve, glossy condition of the skin had disappeared, and the muscles of the thenar eminence were recovering.—Professor ROSE said that he had had several of these cases during the last few years, and many of them had not done satisfactorily. There was often much pain because of the stretching of the nerve in order to bring the ends together, as he had taken much pains to secure end-to-end union.—Mr. RIVINGTON asked if it were certain that the tissue which was reflected down was really cicatricial tissue, and he suggested that it might have been the severed end of the nerve which had become doubled backwards. He asked if any experiments on animals had been performed which confirmed the view that restoration of function would take place if the connecting medium were merely connective tissue.—Mr. PICK, in reply, said that he felt certain that the mass contained cicatricial tissue only, without nerve filaments.

Mr. EDMUND OWEN showed a female infant of nine months, who last January was admitted to the Children's Hospital with Acute Sub-deltoid Abscess. The infant looked extremely ill; axillary temperature 101°; pulse rapid and feeble. Under chloroform, the movements of the shoulder-joint were free; the humerus was thickened just below the tuberosities. The diagnosis made was acute septic inflammation—probably with necrosis—at the diaphysial aspect of the junction cartilage. On an incision being made down to the bone an abscess was evacuated, and a small opening was found leading into the humerus at the surgical neck. This opening was enlarged, two small sequestra were extracted, and a good deal of granulation tissue was scraped out of the expanded shell of bone. During this operation the epiphysis became detached. The cavity was washed out with a chloride of zinc solution and temporarily drained, the upper part of the incision being closed with sutures. The hand was then fixed across the opposite side of the chest, and the arm was secured in dry dressings and a bandage as if for separation of the epiphysis. The infant's temperature quickly dropped; the wound closed; the epiphysis once more became attached to the shaft, and the child has recovered with movable joint and a sound limb. Mr. Owen was of opinion that this case had been on the verge of becoming one of those which were described as acute arthritis of infants, and though he could not adopt the term as a separate pathological entity, he was well aware that arthritis did often follow the epiphysitis. He was in favour of early exploration of the bone in these cases.—Professor ROSE congratulated the exhibitor on the result of the case. He had often thought that the epiphysial cartilage acted as a barrier, preventing the extension of mischief into the joint.—Mr. PICK took exception to the title "acute epiphysitis," which had been used to describe the case. It was not a disease of the epiphysis, but of the growing end of the diaphysis, and not beginning in the cartilage or the epiphysis at all. He did not take a gloomy view as to the ultimate length of the arm, for often in these cases the growth of the cartilage was not interfered with, and shortening did not happen. In one case under his observation, where there was a similar lesion at the upper end of the femur, no shortening could afterwards be detected.—Mr. BATTLE concurred in the view that the disease occurred in the growing end of the diaphysis, and it was fatal because of the tendency there was for the affection

Digitized by Google

to spread through the epiphysial cartilage into the joint rather than to point towards the surface. As for the after-result, they nearly all showed deformity about the joint, with shortening of the limb.—Mr. KEETLEY thought that this condition could rarely lead to shortening, because shortened limbs from this cause were so very rarely seen in after-life. Such an affection might, indeed, even lead to a lengthening of the bone, and he referred to an instance which illustrated this.—Mr. OWEN, in reply, accepted entirely the view that the disease began at the upper part of the diaphysis, near the cartilage; he did not like to call it a diaphysitis, however, as it did not involve the whole shaft. He thought that there were a good many of these shortened limbs about, and that many of them were put down to infantile paralysis. It was usually a chronic disease, and not an acute one, which produced lengthening of the bone.

Dr. COLCOTT FOX introduced a woman aged sixty-six who was the subject of Senile Tuberculosis of the Skin. For six or seven years she had had a lupous condition of the skin of the back of the hand, which had of late assumed a secondary papillomatous character. She had originally struck her hand and inflicted a wound at the time she was nursing her husband and daughter, both of whom died of phthisis. He referred to two other cases: one in a woman of seventy-two and the other in a man aged eighty-two, in both of whom the lesion was on the back of the hand. In two of the cases the parts examined microscopically presented all the characters of tuberculosis, except that bacilli were not found.—Mr. SHEILD said that he had twice seen a cutaneous tubercular lesion in an elderly woman associated with an encysted tubercular ascites. In an elderly man he had seen a localised cutaneous tubercular lesion followed by acute general tuberculosis.—Dr. PASTEUR asked if lupus in younger people could commonly be regarded as arising by inoculation.—Mr. OWEN referred to the case of a post-mortem room porter who had warts on the back of his hand of chronic character, and who eventually died of phthisis.—Dr. FOX, in reply, said that personally he held a strong belief that the large majority of cases of lupus were due to inoculation from an outside source. Laennec also suffered from post-mortem warts and died of phthisis.

Mr. LOCKWOOD showed a healthy-looking woman on whom he had performed Nephrectomy. She had suffered from renal symptoms for the last fifteen years, which had been bad for the last seven. She came under his care in November, 1891, with a loin tumour, pain on micturition, cystitis, and pain in the lumbar region. She was passing thirty to sixty ounces of urine per diem, which was acid and contained one-sixth pus. He cut down by a lumbar incision and found a pyo-nephritic kidney, which he removed. On opening it it was found to contain a large calculus, which could not be felt, and which was only discovered on making a section of the organ.—Professor ROSE agreed in the advisability of attacking these cases from the loin. The great quantity of urine passed was strongly in favour of the other kidney being healthy.

Mr. BATTLE exhibited a girl aged five who, on Feb. 6th, 1892, slipped off the pavement and became crushed between the wheel of a van and the kerb. On examination there was found an irregular fracture of the skull, with considerable depression of bone, the latter being comminuted and measuring 2 in. by 1 in. Trephining was performed, the depressed portions elevated, and the piece removed by the trephine replaced. The pericranium was united by silk sutures, and the wound completely closed, no drainage-tube being used. The patient made a good recovery, in spite of the fact that she also suffered from a green-stick fracture of the right clavicle, a compound comminuted fracture of the right tibia, a compound fracture of the right fibula, and an extravasation of blood into the right iliac fossa.—Professor ROSE had found replacing the disc of bone not to be altogether satisfactory, especially if the piece were large. In one instance he had to remove such a piece on account of the irritation it caused.—Mr. SHEILD thought that the result would be better in young growing children than in adults.—Mr. KEETLEY said that in cases of depressed fracture of the skull it was preferable to use the chisel and mallet rather than the trephine. The portion of bone which was depressed was usually engaged all round the edge of the fracture, and these edges, on being chiselled off, easily disengaged the bone. In a compound fracture where there was dirt in the fissure the chisel would readily clean the fissure as well as raise the fragment. The portion of bone he wished to replace he usually put in a pocket which he cut in the neighbouring skin, and it was kept warm and healthy there until he was ready to replace it.—Mr. WATSON CHEYNE said that he had three times put back crowns of trephine and all with a successful result; but they were all in children, where the bone was very thin and vascular. In two cases the discs were put back whole, and one he cut into small pieces; the latter proceeding he meant to adopt in a future case. He kept the discs of bone in warm boric acid solution until they were required.

Mr. BATTLE likewise showed a woman aged thirty-four who in 1888 underwent an operation for Necrosis of the Clavicle, and a great deal of the bone was removed. The disease was of syphilitic nature, and a large gummatous ulcer over the part healed under iodide of potassium. There was one-third of the clavicle wanting, and there was no attempt at new formation of bone, there being merely a strong fibrous union between the ends of the fragments. Notwithstanding this, it was surprising what good power over the upper extremity the patient possessed.

Mr. MARMADUKE SHEILD showed a case of Spina Bifida Occulta associated with Necrosis of the Foot and Talipes. The patient was a man aged twenty-three, who came under observation on Dec. 21st, 1891. He had lately been an inmate of the Orthopædic Hospital, under Mr. Fisher, and the latter gentleman had operated upon the "club-foot" (talipes equino-varus) with exceedingly good result. A photograph was shown of the feet before operation. When first seen by Mr. Sheild there was a typical perforating ulcer under the left fifth metatarso-phalangeal joint. The orifice was surrounded by thickened, callous corn-tissue, and the probe reached carious bone. A bad corn also existed in a similar position on the right foot. On examining the spine a depression could be seen and felt in the lower lumbar region, and here the arches of the vertebræ appeared to be absent, and there was a growth of dark hair upon the skin. The mother of the patient stated in a letter that the medical man noticed, and spoke of, this condition at birth. She also made the spontaneous statement that for many years the child had no control over the evacuations of the bowels, and it was an interesting point that even now the patient could not restrain his bowels when he had diarrhœa. The talipes was probably congenital, but had got rapidly worse in the last few years. In conclusion, Mr. Sheild referred to the cases of Virchow quoted by Sutton, and pointed out the similarity which existed between many of the cases quoted by Mr. Sutton and the present one. He had reason to believe that many of these cases were overlooked in practice.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Mr. S. F. MURPHY, President, in the chair.

MONDAY, FEB. 15TH.

AFTER the transaction of ordinary business the President, in the name of the Society, presented to S. R. Lovett, medical officer of health of St. George's and St. Giles's, a silver tea service in recognition of his long and valuable services as treasurer.

Boric Acid in Foods.

C. F. CASSAL, F.C.S., then read a paper on the above subject. He was, he believed, the first to demonstrate the presence of boric acid in butter and cream, but it was now a matter of notoriety that, either alone or combined with borax, it was extensively used as such, or in the form of proprietary nostrums for the preservation of milk, cream, butter, meat juices, peptones, and similar preparations, caviar, &c; and also of fish and butcher's meat. It was not in any sense a food, was foreign to the animal organism, and was not necessary for the preservation of any of these articles, which could be effected by other and unimpeachable means. Foods so treated might be "of the substance," but were certainly not "of the nature and quality" expected by the purchaser. There was unfortunately little evidence as to the action of boric acid and the borates on health. In 1887 Dr. Dudfield and he had, at the request of the Vestry of Kensington, made some inquiries and sought the opinion of Sir A. Clark, Sir H. Thompson, and Dr. Lauder Brunton. Dr. Brunton referred to the investigations of Förster, who, from his experiments on dogs, had come to the conclusion that daily doses even of four grains checked

Digitized by Google

digestion, and caused a considerable increase of the unassimilated albuminoids in the fæces, together with a tendency to diarrhœa; and Sir Henry Thompson considered that it could not but be injurious to infants, who would naturally consume the largest proportion of such milk. Förster found it to act injuriously on plant life, checking the formation of chlorophyll. The Local Government Board declined to express any opinion. Hehner did not find it to interfere with the peptonising of albumen conducted artificially, but the conditions of the alimentary canal and of glass vessels were not perfectly similar, and, so far as we knew, all antiseptics were more or less hurtful in normal states of the system. We must always bear in mind the different action of single large and of constantly repeated small doses. The proportions in which he had found it in foods were in butter, 0·5 to 1 per cent.; milk, 7 gr. to the pint; cream about double this; while meat and fish were packed in it or "pickled" in a solution.—Dr. OGILVIE said that last summer he and three friends out yachting had used boric acid for preserving their meat, which they took on board once or twice a week. They never boiled it, and must therefore have ingested about a quarter of a pound each of boric acid in the course of the month. They certainly felt no ill effects.—Mr. WYNTER BLYTH referred to its use in medicine, especially for thursh in infants, and was very doubtful as to any possible harm from it in moderation.—Dr. SYKES said that he had seen large consignments of rabbits imported from New Zealand in ice and boric acid. They were pressed flat, had a most uninviting aspect, and a peculiar "alkaline" odour quite unlike that of ordinary putrefaction. The flesh, he had observed, was remarkably friable. He demurred to Mr. Cassal's statements that germicides must necessarily be poisonous to man and other higher animals—a position formerly held, but now no longer tenable.—Dr. WILLOUGHBY referred to some recent experiments on the sterilisation of milk, an abstract of which he had published in the *International Journal of Medical Sciences*, from which it appeared that boric acid was but a feeble germicide, that borax, like carbonate of soda, neutralised the lactic acid, and that the general result was rather to conceal the changes that did take place than to prevent or even greatly retard them. The friability of the New Zealand rabbits seemed to indicate analogous conditions, and he maintained that the use of boric acid and the borates was to be deprecated, not so much on account of any assumed toxic action of the reagent as from the fact that it concealed incipient decomposition and rendered saleable food that would not be so otherwise, and could not be deemed wholesome. It was thus that the petty dealers carried over to the next day their surplus and stale milk, which they could not, like the larger houses, turn into butter. But in the case of fresh butter and cream it might, perhaps, be looked on as a *bond-fide* preservative.—A MEMBER mentioned that a fishmonger he knew had kept his shop perfectly free from flies all last summer by frequent waterings with a boric solution.—Professor CORFIELD deprecated departing from first principles and discussing probabilities or degrees of ill effects. Boric acid and borax were drugs, perhaps valuable as therapeutic agents, but they were not foods, nor constituents of the body, as salt, or even as the nitrates, phosphates, &c., of the alkalies; and while any doubt existed as to its innocence, boric acid should be prohibited in food.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

Brain of Ornithorhynchus Paradoxus.—Abnormal Condition of Shoulder-joint.—Myology of Rodents.—Abnormal Aorta.

A MEETING of the Society was held on Monday, Feb. 22nd, Sir William Turner, F.R.S., in the chair.

Sir W. TURNER communicated a paper on the Brain of Ornithorhynchus Paradoxus, comparing it with that of echidna, remarking on its lower grade of development and pointing out the great size of the olfactory bulb. Sir William described the brain as having an absolutely unconvoluted external surface, referring certain shallow sulci mainly to the presence of bloodvessels. He referred to certain points on the inner aspect, especially to the posterior connexions of the olfactory bulb and a possible spherical fissure.—Dr. ALEXANDER HILL had also studied the brain of ornithorhynchus, probably from an older subject. He found a well-marked division of frontal, temporo sphenoidal, and occipital lobes, but no convolutions or fissures, with the exception of the rhinal and hippocampal fissures. He remarked also the great size of the olfactory bulb, and described its connexions. The fissure on the inner aspect described by Sir William Turner was probably the homologue of the hippocampal.

Sir W. TURNER communicated for Mr. Hepburn a note on an Abnormal Condition of the Shoulder-joint. The joint was removed from a dissecting-room subject, the main peculiarities being an almost complete absence of the upper part of the capsular ligament, the remains attached to the glenoid cavity exhibiting a smooth rounded margin and atrophic changes in the humerus. The condition was symmetrical, and in addition there was an arthrodial connexion of the acromion process on the right side. A short discussion took place, in which Messrs. Thane, Anderson, Howes, and Curnow took part, the general opinion being expressed that the condition was pathological.

Mr. F. G. PARSONS read a note on Some Points in the Myology of Rodents. Mr. Parsons referred to the bilaminar arrangement of the panniculus carnosus in rodents, and to its supply by a large nerve corresponding to the internal anterior thoracic of man. The mingling of the fibres of the deep layers of the panniculus with the pectoralis major, a bundle actually passing between the abdominal and sternal portions of the latter muscle, suggests the possible origin of the pectorals as a specialisation of the deep layer of the panniculus. This would explain also the relation of the occasional sternalis and axillary arches to the pectoral muscles, all being developed from the same layer of the panniculus. The arrangement of the adductor magnus and semi-membranosus in the agouti suggests that the adductor magnus in man represents both the great adductor and a slip of the semi-membranosus, the latter segment being that internal to the adductor arterial canal and supplied by the sciatic nerve. The rectus capitis posticus major in the guinea-pig was found to consist of two distinct slips on three occasions; this arrangement had not been found in any other rodent.

Mr. F. C. ABBOTT showed two specimens of Abnormal Aorta, one a right arch, the branches arising in the following order: Left carotid, right carotid, right vertebra, right subclavian, left subclavian; the second, a left arch with the carotids arising by a common trunk, the right vertebral arising from the right carotid beyond the carotid trunk, the left vertebral, then the left subclavian, and lastly the right subclavian. Mr. Abbott also showed a Pulmonary Valve, with four cusps.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Section of State Medicine was held on Feb. 19th, Dr. Cosgrave, President, in the chair.

The Control of Inebriates.—Dr. COSGRAVE, having dealt with the varieties of inebriety and described the working of the Inebriates Act, suggested that certain improvements were required. Voluntary entrance into an inebriates' home should be made much easier. The necessity of appearing before two justices was especially odious. Delays and disappointments arising from this requirement kept many cases from treatment. It would, indeed, make the Act much more workable if entrance was still more simplified and no appearance before a magistrate was required. With all the safeguards for inspection and appeal that are in the present Acts, no harm could arise from entrance into a retreat being made comparatively easy. There should be power to send people to inebriate asylums, this power to be invoked by the person's family or friends or by the public authorities. Provision for poor cases is urgently needed. This would of course cost money, but if it led to the cure of inebriates it would lessen police court, workhouse, prison, and lunatic asylum charges. The cost need not fall on the general body of the ratepayers. The inmates should be required to work to help to meet the cost of their support. The Inebriates' Home of King's County, New York, gets 12 per cent. of the licence moneys, an example which might well be followed in this country. There are defects in the present Acts which unnecessarily added to the difficulties of the licensee. Thus a patient could

Digitized by Google

easily escape if he chose, and the licensee had no right to use force to prevent him. The part of the liquor traffic which consists in encouragement of drunkenness should be suppressed. In Prince Edward's Island when proper notice in writing is given to any dealer in intoxicating liquor that a person is addicted to drink, he is not allowed to sell him any intoxicant. The penalty for the first offence is a fine of not less than £5; for subsequent offences a fine of between £5 and £10, and imprisonment for a period not exceeding thirty days. The author had brought the subject again before the Section, as he believed that in many cases inebriety was a disease closely allied to insanity and susceptible of successful treatment, if power was given to keep the patient from drink for a sufficiently long period, and that therefore the sooner the case was taken in hand the greater was the probability of cure.—Dr. DAVYS was of opinion that the only successful treatment or cure of the intermittent drinker was that the family physician should, with the approval of the family of the patient, employ a strong male attendant for the inebriate, and by physical force prevent him taking any alcohol, the patient to be kept in his house. Much greater privacy was thus observed than by sending him to a retreat, and having to bring him before a magistrate. The inebriate, when returning to his sober state, usually fully approved of the course adopted by his physician. Dr. EDGAR FLINN quite agreed that the difficulties in getting dipsomaniacs into retreats under the Habitual Drunkards Act were made too stringent. It was a pity that the Habitual Drunkards Act was not applied to Ireland, for it certainly was required, and would act most beneficially. Persons addicted to drink were a class very difficult to treat by drugs; the radical cure, no doubt, was to remove them to some place where they would be prevented from obtaining drink; in fact, in some instances, they might with propriety be placed in asylums.—Dr. J. W. MOORE instanced three cases of intermittent inebriety which had come under his observation, and expressed the opinion that physical restraint was a much more reliable means of treatment than any medicinal remedies. The whole question of the control of inebriates was well worthy of the Legislature of the country.—Dr. J. DONNELLY agreed with the previous speakers as to the value of physical restraint in the treatment of inebriates and the necessity which existed for greater power in using it.—Dr. COSGRAVE, in reply, said that intermittent inebriety was undoubtedly the most interesting form from a scientific point of view. Dr. Davys' treatment of restraint by a stalwart attendant was good, if the patient would submit to it; but there was no power to compel him to do so. Easy admittance into an asylum for inebriates for a short period exactly met the requirements of such cases, and afforded a chance of tiding over attacks. Inebriety often caused neuroses in the descendants, sometimes whole families being affected with hysteria, epilepsy, inebriety, &c. In one case he (Dr. Cosgrave) had seen inebriety once in three generations. A lady, aged nearly seventy, suffered from intermittent attacks, her daughter died of delirium tremens at about thirty, and the granddaughter was seen under the influence of drink when only fifteen years old.

Pollution of the South-eastern Foreshore of Dublin.—Dr. EDGAR FLINN read a paper on the pollution of the south-eastern foreshore of Dublin. He pointed out that the pollution at Dublin, extending from Merrion to Kingstown and Sandycove, not only existed but was increasing, and that, although several partial attempts had been made to remedy the state of affairs, nothing radical had been effected. Eight main sewers and thirty minor ones at present discharged into the sea at this locality. He advocated a deep-sea outlet. In addition, he recommended an intercepting sewer, in which the sewage was to be collected and then discharged at about 600 feet from the shore, at a depth of 30 feet below the level of sea water. He concluded his paper by a criticism of the present methods of disinfecting sewage, and referred to that of Messrs. Adeney and Parry, known as the oxygen process, which had the advantage of precipitating the solid matter of sewage without the addition of precipitative chemicals.—Dr. DONNELLY remarked that, as precipitation has been so successful in many places, it could be adopted at the Salthill outfall, and avoid polluting the sea so close to the best bathing-place near Dublin.—Dr. COSGRAVE strongly urged the importance of not carrying out new drainage into the sea, but of substituting precipitation as used so successful at Drumcondra, and as about to be introduced in Dublin.

BRADFORD MEDICO-CHIRURGICAL SOCIETY

TUESDAY, MARCH 1ST.

ROBT. MERCER, M.R.C.S., President, in the chair.

Aortic Aneurysm.—Dr. MAJOR showed a mechanic, aged thirty-six, the subject of Aneurysm of the first part of the Aorta. Trouble began with sudden paroxysmal pains in the right side and arm about nine months previously; untreated syphilis eighteen years before. A large pulsatile tumour presented between the second and fourth ribs on the right sternal margin; there was systolic and loud diastolic bruit, heard loudest over the tumour, also down the sternum and at the back; heart hypertrophied. Pupils unequal, but no other pressure symptome. Treatment consisted of rest, morphia, large doses of iodides, little fluid, but otherwise unrestricted diet. The patient was very much improved.

Peripheral Neuritis.—Mr. PETTITT showed a clerk, aged thirty-three, who had resided some time at Lagos, West Africa. Illness began acutely with vomiting after dining with a friend, who suffered similarly, but quickly recovered. Patient next day found he could not stand, and nine months after the onset was brought to England and carried to the infirmary. He supposed himself suffering from sasswood poisoning, which is said to produce a rapid paraplegia, loss of use of arms, and death. He had suffered from ague, rheumatic fever, gleet, and alcoholic excess; was profoundly anæmic; could hardly stand; little power in limbs; double wrist- and foot-drop; no knee-jerks; atrophy of interossei and muscles of the thumb; tenderness on squeezing calf muscles; reaction of degeneration in muscles of thumb and extensors of legs; no lead line; no mental peculiarities; urine contained a trace of albumen, and lead was detected in it.—Dr. MAJOR said that whatever the cause, the case was undoubtedly one of peripheral neuritis, and iodides were given and massage regularly applied, and this last had probably done most to get him well again.—Mr. OFFORD said poisoning by sasswood or sassywood was usually fatal on the second or third day, and resembled tetanus somewhat in symptoms.

Melanotic Sarcoma of Brain.—Mr. PETTITT read notes of a case in which a man aged forty-three had his eye removed some months after a severe blow. On admission to hospital seven months later he was totally deaf and blind, knee-jerks gone, and face paralysed. He had a tetanic spasm about ten days before death. Post mortem numerous inky black growths were found over the brain.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, MARCH 4TH.

Mr. ROBERTS, President, in the chair.

Radical Cure of Prostatic Enlargement by the Galvano-cautery.—Mr. BRUCE CLARKE read a paper on the above subject. After alluding in general terms to prostatic enlargement, he pointed out that, though obvious enough when the prostate was of considerable size, the disease was not easy to diagnose in its slighter varieties, which, as the result of post-mortem examinations showed, formed a large proportion of the cases as a whole. He had seen a good number of cases in which the patient had died from the results of cystitis, set up by prostatic enlargement, in which the actual obstructing piece of prostate was but small and seemed to come down like a little valve and block the urethra during the act of micturition. Of late years the prostate had been removed by the supra-pubic method when enormously increased in size. In such cases the galvano-cautery was absolutely useless, but in the slighter degrees of enlargement he had found it most useful. He described the method of using the instrument, and also of illuminating the interior of the bladder.—Dr. LEWIS JONES described the accumulators for heating the galvano-cautery and their construction at some length.

Dr. FULLERTON, for Mr. Poland, showed a young woman with a small tumour on the outer side of the right leg, three inches below the knee. It had been noticed for three months, and was as large as a small walnut. It disappeared under chloroform anæsthesia, but returned, and was evidently a localised spasm of the muscles.

Dr. ERNEST CLARKE showed the brain of a man admitted

Digitized by Google

into the Miller Hospital in a comatose condition, the result of a fall downstairs. He had incised a large swelling over the occiput with the intention of trephining in case depressed fracture was found. No fracture was discovered, and the man died three hours later. Post-mortem examination revealed extensive fracture of the base with laceration of the brain and hæmorrhage.

Reviews and Notices of Books.

The Comparative Anatomy of the Domesticated Animals. By A. CHAUVEAU, M.D., LL.D. Translated and Edited by GEORGE FLEMING, C.B., LL.D., F.R.C.V.S. Second Edition. London: J. and A. Churchill. 1891.

THE second edition of this standard text-book of veterinary anatomy will be welcomed not only by veterinary students but by all who have occasion to require a thorough and accurate description of the following animals: dog, cat, rabbit, pig, horse, ass, mule, ox, sheep, goat, common fowl, guinea fowl, turkey, pigeon, goose, and duck. The work contains 1084 pages, which are divided into nine sections or books, each treating a special system. The plan adopted is to take a type, which is most commonly the horse, and to describe each part accurately and thoroughly. This description is then compared at some length with the corresponding region in man, and then more briefly with the other animals on the list. The first book is devoted to the Locomotory Apparatus, and altogether gives the reader an accurate and clear idea of the osteology and myology of the animals treated. But here our attention is drawn to a defect that runs all through the book: the writer, in deciding on what names he shall give the various parts, does not always consider whether these names are used for the same parts in modern human and comparative anatomy. As an example of what we mean we will quote the description of the horse's skull. Here the foramen lacerum basis cranii is said to be divided by a ligament into an anterior and posterior foramen lacerum; but human and comparative anatomists generally recognise three lacerated foramina in the skull—anterior, middle, and posterior,—the anterior being also called the sphenoidal fissure and the posterior the jugular foramen. A student, therefore, accustomed to the use of modern anatomical nomenclature would run the risk of understanding that in the horse the sphenoidal fissure and jugular foramen were confluent.

The second book treats of the digestive apparatus, the third of the respiratory, the fourth of the urinary, the fifth of the circulatory, the sixth of the nervous, the seventh of the skin and sensory organs, and the eighth of the organs of generation. The ninth book is devoted to embryology, and gives a very complete and lucid statement of the changes that occur in the development of the fœtus. The work contains 585 illustrations, which are gathered from a great variety of sources, and of course are not all of equal value; 270 are Dr. Chauveau's, and these strike us as being the most valuable, and as showing the main features of the parts pictured most clearly. Most of the human osteological figures are borrowed from Wilson, while the descriptions of human neurology are accompanied by Hirschfeld's and Léveillé's illustrations; in addition to these Heath, Quain, Gray, and Holden have been borrowed from for the human anatomy, and Carpenter, Krause, Kölliker, Bowman, and Ecker for general histology. About sixty of the illustrations are original, and among them are some valuable sections showing that the modern tendency towards topographical teaching in anatomy is duly appreciated. The only drawback to these last named is the fact that the parts are numbered with almost microscopic figures, which are often placed upon the drawing and among the shading in such a manner as to make them very difficult to trace without the best possible light and eyesight. The embryological portion of the work is illustrated in a very copious and judicious manner, so as to materially assist the student who is trying to grapple with this most difficult portion of anatomy. The pictures are largely borrowed from Balfour and Kölliker. At the end of the work is a very comprehensive index, which greatly adds to its value. We heartily welcome the translation, not only as a standard work for English veterinary surgeons, but as a valuable book of reference for comparative anatomists.

Differences in the Nervous Organisation of Man and Woman. By HARRY CAMPBELL, M.D. London: H. K. Lewis.

IN the preface to this work it is stated that it was intended to discuss the subject with particular reference to the pathological aspects of the question, but the necessity, in order to make the work in any way satisfactory, of tracing the origin of physiological differences, and of discussing their bearings upon pathological problems, has resulted in a larger work than was intended. The book is one of nearly 400 pp., and it is divided into three main parts. The first deals with the evolution of sex, and the most important pages are those in which the views of Geddes and Thomson, with reference to the morphological differences between the sexes, and their explanation, are subjected to a searching criticism. While not denying that most people will probably grant that anabolism and katabolism are the characteristics of the female and male sexes respectively, Dr. Campbell, in a few pages of closely reasoned and logical writing, clearly shows that this characteristic of the sexes and of the sexual elements is not adequate to explain sexual variations. The second part of the book is devoted to explaining the variable incidence of different forms of nervous disease on the assumption that anabolism and katabolism are characteristic of the sexes, but there is a tendency to make too free a use of those qualities and to minimise the effects which the differences in the modes of life of the two sexes and the greater incidence of syphilis upon males are likely to produce. An interesting and suggestive chapter is that in which the sexual instinct in man is compared with that in woman, and the definite conclusion is reached that this instinct is much less strong in the woman than in the man. The chapter discussing a menstrual rhythm in the male is crude and unsatisfactory. The third and last part of the book is almost purely psychological, and deals with various problems ranging from the origin of sensations to freedom of will. Here the individuality of the author is more evident than anywhere else in the book, and the manner in which the different questions are discussed shows his intimate acquaintance with the various views which have been held on the subject. In the fascination of the subject itself, the psychological differences as manifested in the sexes have not been so prominently kept in view as we should have anticipated.

The book as a whole is to be regarded more as a series of papers, highly interesting and suggestive undoubtedly, rather than as a work with any very definite result; and from the nature of the questions discussed, this was to be expected. But this character causes the work to lack cohesion, which is to be regretted, and which will make its influence less than if it had been more condensed.

Transactions of the Seventh International Congress of Hygiene and Demography. Edited by C. E. SHELLY, M.D. Vol. XII.: Municipal Hygiene. Royal octavo, pp. 183. London: Eyre and Spottiswoode.

THE Transactions, of which this is the first volume to appear, are being published in thirteen volumes, the number of each volume being the same as the number of the Section

Digitized by Google

to which it is devoted. Hence it follows that vol. xii., in which there are no discussions to be reported, is the first to be issued. The origin and objects of the present volume are tersely given in a short introductory note which bears the signature of Dr. Poore, the secretary-general, and is to the following effect:—"To the Corporation of Dundee is due the credit of originating a suggestion made during the earlier part of the year, in response to which a number of municipal bodies supplied the honorary secretary-general of the Congress with brief reports relating to their vital statistics and corporate history, and embodying the results of local sanitation. These communications—which were obviously unsuited, and were not intended, to form a subject of discussion by the Congress—are collected in the present volume, and, in order to facilitate reference, have been arranged in alphabetical order under the names of the cities and towns to which they severally refer. They thus present, in a compact and accessible form, a considerable mass of information, which can scarcely fail to prove valuable as well as interesting. For, dealing as they do more or less fully with all the great questions of modern sanitation, they indicate some of the many ways in which these problems have arisen, the causes which have operated to make them urgent, and the methods by which they are being successfully solved by communities varying within wide limits of population and of very different rates of growth, existing under a diversity of social conditions, and occupying areas that differ greatly in extent, in configuration, and in climate." The volume contains reports from thirty-five municipalities and sanitary authorities—viz., Aberdeen, Andover, Belfast, Birmingham, Blackpool, Bournemouth, Brighton, Cardiff, Croydon, Dundee, Ealing, Edinburgh, Glasgow, Gloucester, Hanley, Huddersfield, Lancaster, Leeds, Liverpool, Morecambe, Newcastle-upon-Tyne, Paignton, Preston, Richmond, Ryde, St. Helens, Salford, Wallingford, Wolverhampton, Ahmedabad, Bombay, Calcutta, Rangoon, Auckland, N.Z., and the colony of South Australia. Each body was left free to choose its facts and to arrange them as seemed best, and the result is that the reader has the advantage of studying a great variety of practical sanitary measures, which should have considerable interest for all those who are engaged in official sanitary work. Many of the papers are illustrated by maps and plans, which, although not showing much detail, are sufficient to give an idea of the situation and lay of the locality dealt with. All who are interested in municipal hygiene may obtain the volume by sending the price (2*s.* 10*d.* post free) to the publishers, the Committee of the Congress having wisely determined to sell each volume separately, and for a uniform price. To members of the Congress this, as well as the other volumes, will be supplied gratuitously when all are completed.

OUR LIBRARY TABLE.

The Simulation of Hysteria by Organic Disease of the Nervous System. By THOMAS BUZZARD, M.D. Lond. London: J. & A. Churchill.—We referred some time ago to Dr. Buzzard's interesting presidential address to the Neurological Society. This work has that address as a backbone, but a considerable amount of fresh material has been added, rendering the little book as complete and concise as is to be expected under the circumstances. Dr. Buzzard has undoubtedly done a great service to practical men by bringing so forcibly under their notice the characteristics of a large and important class of cases in which the diagnosis offers much difficulty, and in which mistakes are productive not only of disappointment and chagrin to the practitioner, but also of grave injustice to the patient. The work, as we have said, is as complete as its nature requires, and is well worthy of careful study.

Manipulation of the Microscope. By EDWARD BAUSCH. Illustrated. Bausch and Lomb Optical Company, Rochester, New York, and W. P. Collins, London. 1891.—We have before us a copy of the tenth thousand of Edward Bausch's little book on the microscope. As one would expect from the accuracy of his formulæ, the results of which are seen in his objectives, the work is thoroughly practical, and anyone who carefully reads through this book will have an amount of knowledge of technical detail and of the method of working with the microscope that can be obtained from no other book of the same size. The hints on "How to select a Microscope" are very valuable, though they refer, of course, to Bausch and Lomb's special catalogue and to high-class microscopes, rather than to those within the reach of the student. We can recommend this little work both to those who wish to obtain information about the microscope and to those who wish to have, in handy form, the more important data useful to the microscopist.

"Hors de Combat"; or, Three Weeks in a Hospital. Founded on Facts. By GERTRUDE and ETHEL ARMITAGE SOUTHAM. Illustrated. London, Paris, and Melbourne: Cassell and Co.—This handsome quarto is probably intended to give an idea of the way in which hospital routine strikes a casual patient, who, by the way, is in this instance a baronet. It sets forth in enthusiastic terms the qualities of Sister Agnes and Nurse Graham during the three weeks of the baronet's stay in the institution. The accident, a broken arm and a scalp wound, has rendered the patient unable to shoot grouse on the Scottish moors—placed him, so to speak, "hors de combat." The literary style abounds with tropes and figures, some of them correct and others fantastical. Gruesome cases of double amputation, of delirium tremens, and suicide are detailed in as racy and circumstantial a manner as the subjects will permit of. Regarding the nurse, due prominence is given to the "picturesque white cap tied becomingly under the chin," to her ingenuity, and her unfailing good temper. The book is handsomely got up by the printer, and is embellished with excellent illustrations, which are a credit to the various artists who photographed them and prepared them for the press. In these respects we have nothing but praise for it. Our difficulty has been in discovering any good reason why a baronet with a broken arm, having been taken to an institution of this kind, should have been kept there for twenty-one days at the rate of three guineas a week, when he might have been sent home and the bed occupied by a necessitous patient. It appears that he was made so comfortable in his hospital quarters that on getting home again he "wished to goodness he was back at the hospital." As a matter of fact, he did return on the first opportunity, and was conducted through the whole institution. The tale finishes somewhat abruptly by the secretary receiving from the grateful baronet a cheque for £1000, as a kind of conscience money.

Higiene de la Vista y Causas de la Ceguera. Por el Dr. JUAN GELPI Y JOFRE, Profesor Libre de Oftalmologia. Barcelona: Tipografia, *La Academia.*—This work on the Hygiene of the Sight and the Causes of Blindness is not intended to teach medical students ophthalmology, but to give the public, and perhaps especially persons in authority and those having charge of children, some idea of the most common forms of eye diseases and to show them how they may be guarded against. A number of statistics—somewhat out of date, it is true—and a map are given showing the proportion of blind to the general population in the different provinces of Spain. From these we see that the worst province is Almeria, where the percentage of blind is 0·379; in Madrid it is 0·2294. The province where there are fewest blind is Tarragona, where the percentage is only 0·0524.

The Journal of Anatomy and Physiology. Conducted by Sir GEORGE HUMPHRY, Sir WM. TURNER, and J. G. MCKENDRICK. Vol. XXVI., Part II. January, 1892. Williams and Norgate.—The following are the more important papers contained in this number:—1. David Hepburn: The Comparative Anatomy of the Muscles and Nerves of the Superior and Inferior Extremities of the Anthropoid Apes, with a plate. 2. D. M. Greig: Congenital and Symmetrical Perforation of both Parietal Bones. 3. A. E. Wright: A Suggestion as to the Possible Cause of the Corona observed in certain After-images. He attributes it very sensibly to changes in the accommodation during fixation. 4. A. A. Kanthack: Complete Cervical Fistulæ. 5. R. Shufeldt: Concerning the Taxonomy of the North American Pygopodes, based upon their Osteology. The pygopodes, he thinks, are restricted to the Loons and Grebers. 6. Vaughan Harley: Experimental Pathological Evidence, proving the existence of Pancreatic Diabetes. 7. A. N. McGregor: The Repair of Bone, with special reference to Transplantation, with a plate. 8. T. P. Anderson Stuart and Alexander McCormic: The Position of the Epiglottis in Swallowing. 9. James Musgrove: Bifurcation of the Femoral Artery, with subsequent reunion, with a plate. 10. James Musgrove: The Bloodvessels of the Retina, with a Method of Preparation for Lanthorn Demonstration, with a plate. 11. Louis Robinson: On a Possible Obsolete Function of the Axillary and Pubic Hair-tufts in Man. He thinks these tufts may be the traces of the tufts by which young apes hang beneath the body of the mother. 12. Sir William Turner: Notes on some of the Viscera of Risso's Dolphin. 13. The Minute Anatomy of the Central Nervous System according to Golgi's method, translated from several foreign journals by William Aldren Turner.

A Winter Cruise in Summer Seas: "How I Found Health." By CHARLES C. ATCHISON. London: Sampson Low, Marston, & Co.—This book consists of a diary of two months' voyage in the R.M.S.P. Co.'s ss. *Clyde*, from Southampton, through the Brazils, to Buenos Ayres and back, at a cost of £100. The volume has at least three merits—the superiority of its typography; the excellence and abundance of its illustrations, some of which are not without a considerable spice of humour; and the gossipy and entertaining style of the narrative. It is a book eminently calculated to help to while away an idle hour. It will also be useful to any who may need guidance in the selection of a desirable method of avoiding part at least of the trying winter climate of the British Isles.

Analytical Records.

MALTED GERM BREAD.

(JOHN BATES, SOUTH NORWOOD.

"MADE from the entire grain, free from bran, and containing a small quantity of malt flour" are the statements made, and to which, according to our examination, we can take no exception in regard to this excellent specimen of bread. Analysis showed unusual richness in nitrogenous constituents, as well as in valuable soluble phosphate, the gluten calculated on the nitrogen found amounting to 6·96 per cent., and the ash to 0·94 per cent. Moisture amounted to 43·35 per cent. Barley starch was recognised under the microscope. The bread was characterised by a marked nutty and agreeable flavour, and its value as a food is doubtless enhanced by the commendable plan of selecting only the choicest materials for its preparation.

AMPLOSIA—PURE UNFERMENTED JUICE OF THE GRAPE.

(AMPLOSIA KELLEREI, H. KAUL, LANDAU, RHENISH PRUSSIA.)

There is now a particle of evidence, judging from taste and chemical analysis, that this is not, as stated, the pure unfermented juice of the grape. It is perfectly free from alcohol, and yields on analysis 21·11 per cent. extract and 0·28 per cent. mineral matter. Unfortunately the presence of some antiseptic is absolutely necessary to preserve the liquid from fermentation or decomposition. We had no difficulty in extracting a crystalline substance, which readily sublimed on heating, and yielded when neutralised a buff-coloured precipitate with perchloride of iron. Amplosia forms a very palatable drink, especially when mixed with soda water; but the presence of an antiseptic may afford ground in the opinion of many for objection to its constant use.

THE PURE BEEF COMPANY'S PREPARATIONS.

(OLD TRINITY HOUSE, 5, WATER-LANE, GREAT TOWER-STREET, E.C.)

The varieties of food stuffs prepared by this company are not few, as, in addition to ordinary concentrated beef extract, essence, and tea, certain other useful meat preparations have been submitted to us. Clear and thick household stocks for thickening soups, concentrated beef *à la mode* for the quick preparation of a hot tasty dish, and meat lozenges as a portable form of nourishment, may be selected as examples. The essence of beef is a clear, thin, amber-coloured jelly, which on analysis gave the following results: Moisture, 88·43 per cent.; mineral matter (chiefly phosphate), 1·15 per cent.; organic matter rich in nitrogen, 10·42 per cent. Extractum carnis is a solid extract intended to increase the nourishing and stimulating qualities of soups or gravies, and to lend them a rich meaty flavour. It is soluble to a nearly clear solution, and an analysis gives the following results: Moisture, 29·08 per cent.; mineral matter (8·56 per cent. (consisting chiefly of phosphate); organic matter (containing nine parts of nitrogen), 62·36 per cent. The composition of the concentrated beef-tea is excellent. Both microscopical and chemical examination showed it to contain all the valuable principles of good beef-tea—that is, stimulating extractives as well as nutritive fibrine and albumen. Submitted to quantitative analysis the concentrated beef-tea gave the following factors: Moisture, 22·80 per cent.; mineral matter, 9·02 per cent.; organic matter (containing nearly ten parts nitrogen), 67·18 per cent. It is needless to point out that preparations of this character will serve many useful purposes.

REED & CARNRICK'S PREPARATIONS.

(REED & CARNRICK, NEW YORK; AND J. M. RICHARDS, 46, HOLBORN-VIADUCT.

SOME years ago we had occasion to report favourably upon certain admirable products of this firm, and recently we have had submitted to us further interesting and new preparations, the results of the examination of which are well worthy of record. Liquid pancrobilin, as its name indicates, contains the agents which prepare food for assimilation in the duodenum. It is a clear, syrupy, brown fluid, slightly alkaline to test-paper, and sweet at first to the taste and then persistently bitter. After acidulation with sulphuric acid, ether extracted a body which gave the well-known bile reaction with strong sulphuric acid and syrup (Petenkofer's test). Emulsion of starch was readily liquefied, and slowly though distinctly converted. According to other reactions the preparation contains glycerine and spirit. On suitable treatment the pancrobilin pills gave reactions confirmatory of the presence of both constituents—ox bile and pancreatin; while from the compound pancrobilin pills—into the composition of which nux vomica, damiana, extract of colocynth and quinine enter—the alkaloids of nux vomica and quinine were successfully extracted and identified. Lacto-preparata is described as artificially prepared human milk and sterilised, in which the tough character of the caseine is so modified that it will no longer coagulate into hard curds. It has probably therefore been malted or partly digested with diastase, for under the microscope a few cells of barley starch were

Digitized by Google

recognised. On analysis lacto-preparata gave the following results:—Moisture, 1·7 per cent.; fat, 0·6 per cent.; mineral matter, 5·2 per cent. (mainly phosphate of potassium); sugars and albuminoids, 92·5 per cent. Lacto-cereal food is a somewhat complex mixture, and consists of partly digested milk powder, starch, dextrin, malted barley, desiccated bananas, cacao butter, and manna. It is characterised by a very agreeable flavour, and evidently contains a rich proportion of nourishing and probably easily digestible materials. Still more novel are the kumysgen tablets made by this firm, which, when dissolved in water, yield a kind of effervescing kumyss (koumiss). The tablets consist of small cylinders which slowly dissolve in water with effervescence, and by putting twelve in a bottle of water provided with a screw stopper, an effervescent milk may be obtained. The liquid so prepared is sweet and resembles fresh milk. The greater part of the caseine is apparently in solution, as on addition of acid, clots at once separate. These preparations furnish unmistakable evidence of the desire on the part of the manufacturers to place in the market products of a highly scientific kind, and this being so, we may confidently recommend them to the notice of the profession.

MENTHOL AND EUCALYPTUS COMPOUND.

(THOMAS CHRISTY AND CO., 25, LIME-STREET, E.C.)

This is an interesting preparation, occurring in beautiful colourless, needle-shaped crystals, and obtained from menthol and eucalyptus. Soluble in spirit and insoluble in water, it melts at a low temperature, and the menthol may be sublimed and partly separated. It gives off a fragrant and stimulating smell when placed in hot water, and the vapour so obtained may prove of value in the treatment of disease by inhalation.

THE "MORSTADT" CACHET APPARATUS.

(THOMAS CHRISTY AND CO., 25, LIME-STREET, E.C.)

We have received from the above firm a very useful and simple device known as the "Morstadt" apparatus for the ready preparation of cachets containing an exact quantity of any drug. It consists essentially of two bright metal plates fitted with a hinge, and closing like a book. Each plate contains twelve perforations, which are situated exactly over one another when the plates are closed. The plate that folds over is charged with empty cachets, while the other plate is charged with cachets filled carefully with a definite weight of medicament. A third plate, attached by a hinge, serves to cover the cachets when charging. After the cachets are filled, the empty ones in the right hand plate are moistened by means of a wet roller. The right hand plate and the middle plate are then brought together, and the cachet containing the drug, now securely sealed, may be taken out, and is then ready for use. We have examined the material of which the cachets are composed It consists of the purest rice paper, and is readily soluble and quite neutral to the taste. Those who look upon this method of administration with favour may now enclose medicaments by this simple contrivance in cachets for themselves, and thereby secure the exact dose of a given medicament, of the purity of which, moreover, they can be more certain. These are obvious advantages which not a few practitioners may desire to obtain.

KEFEER.

(THE CIRCASSIAN KEFEER FACTORY, 71, SWANSCOMBE-ROAD, CHISWICK, W.)

Kefeer is the interesting product obtained when cow's milk is fermented. It contains less caseine and milk sugar than fresh cow's milk, while alcohol (from 1 to 1·5 per cent.), lactic acid, hemi-albumen, lacto-syntonin, and peptones are found as the result of fermentation. As fermentation proceeds more of the caseine is digested, presumably by the lactic acid, and the conversion of the sugar of milk into alcohol, carbonic acid, and lactic acid continues. The remaining casein is precipitated in fine flakes, the size of which is not increased by the action of the gastric juice. The preparation above gave on analysis the following results: Total solids, 8·42 per cent.; fat, 1·30 per cent.; ash, 0·57 per cent. The sample has evidently been prepared with care, and it may be used with confidence in those ailments for which koumiss is esteemed valuable. Kefeer is somewhat thick, but of uniform consistence and free from lumps; it has a sour though not disagreeable taste. It is believed to fulfil an important indication in infant feeding—namely, the breaking up of the curd of cow's milk without introducing indigestible matter into the infant's stomach. Like koumiss, it has been observed to exert either a diaphoretic or a diuretic action, and to be specially useful in cases of general defective nutrition.

New Inventions.

THE GODALMING FLEECY HOSIERY.

SOME time ago we received specimens of their fleecy goods from Messrs. Nevill and Co. of Godalming. The various articles supplied—abdominal belts, shirts, hose, &c.—are made with the backs or plain parts of cotton, for the sake of cheapness, and also to hold the wool firmer. The wool itself is specially prepared by hand, to secure greater elasticity than would be obtained after the use of machinery. The wool is selected so that from its nature it may remain soft and elastic as long as possible. For this reason no chemicals are used in its preparation. The abdominal belts are manufactured of a natural-coloured wool and a natural all-wool webbing, so that the front also forms a soft and warm support to the abdomen. The shirts, vests, pants, socks, and knee-caps are kept in stock, of the usual sizes, and any, from the smallest to the largest sizes, can be procured on application. The fleecy webbing is also supplied by the yard, and can then be easily adapted by a needlewoman. We have made prolonged trials of examples of this hosiery. Certainly in cases of rheumatism, rheumatoid arthritis, lumbago, sciatica, coldness of the lower extremities, &c., it gives great comfort to the wearer. Old people find it of great use, and sufferers from lumbago speak very strongly in its praise.

NOISELESS COAL VASE.

THIS will be found to be most useful if not absolutely necessary in many sick-rooms. There is nothing more painful or distracting to a patient whose nervous system is enfeebled and rendered excitable by disease than the banging of coal-vase lids or the dropping of pieces of coal when the sick-room fire has to be replenished. Messrs. Treggon and Co., of 19, Jewin-street, E.C., have, by a simple modification of the ordinary coal vase, succeeded in doing away with the distracting noises which often accompany the use of the ordinary coal vase. It is so arranged that it can without noise be opened and shut and wheeled about the room, and the coals can be lifted out of it and placed on the fire without the least sound being heard. The improvement is undoubtedly one which medical men can recommend and which will be appreciated by both nurses and patients. In the case of students also and authors, say of the temperament of the late Thomas Carlyle, it is impossible to exaggerate the amount of mental acerbity which will be spared by the employment of this simple and elegant novelty.

THE LANCET.

LONDON: SATURDAY, MARCH 26, 1892.

WE cannot but feel gratified at Mr. PARTRIDGE'S persistence in appealing to one Court after another for judgment against the Medical Council with regard to its action under the Dentists Act in erasing his name from the Dentists' Register. By such persistence he has brought into clearer form and expression the nature of his offence and the real powers of the Medical Council, as "a domestic forum"—a "domestic tribunal" (using the language of the Master of the Rolls), to purge the dental profession of sins that would discredit it, and lower its character in the estimation of the public. The facts of Mr. PARTRIDGE'S case are very simple. He was on the Dentists' Register in virtue of a dental diploma from the Royal College of Surgeons of Ireland, 1878. On obtaining this diploma he undertook to his College not to attract business by advertising or any other unbecoming practice. Nevertheless he did so, and continued to do so after the remonstrance and repeated warnings of his firm but merciful College. In 1885, for this behaviour of Mr. PARTRIDGE, the College withdrew or cancelled his diploma. In June, 1886, the General Medical Council ordered the erasure of his name and qualifications in consequence of his name having been removed from the list of licentiates of the Royal College of Surgeons of Ireland. In June, 1887, the High Court of Justice granted a *mandamus* to restore his name to the Register, on the ground that the Council had not, before removing the name, investigated the case for itself, as required by the Dentists Act, but had simply acted on the procedure of the Irish College, duly reported to them. This decision of the High Court of Justice left intact the right, and even the duty, of the Council to form its own opinion of Mr. PARTRIDGE'S conduct in the light of Section 13 of the Dentists Act, and to act accordingly. In the November following, the Council, on the report of the case by its Dental Committee, proceeded to a consideration of it. Mr. PARTRIDGE had been summoned, but did not appear either in person or by any representative. The Council resolved that he had committed the offence charged of wilfully violating the declaration not to attract business by advertising, that in the opinion of the Council this is disgraceful conduct in a professional respect, and that the registrar be instructed to erase the name from the Dentists' Register.

The trial on which we are commenting before the Court of Appeal is the last of several attempts to put Mr. PARTRIDGE'S conduct in a different light, and to have the judgment of the Medical Council set aside. No lawyer will disparage the strength of a Court composed of the Master of the Rolls, Lord Justice FRY, and Lord Justice LOPES. Their judgment is exceedingly clear, and involves not only the complete failure of every contention set up by Mr. PARTRIDGE'S counsel, but a strong expression of approval of the course pursued by the Council. The Master of the Rolls ended his judgment by these significant words: "I cannot part with this case without saying that so far from doubting as to whether they (the Council) were right or wrong, I am perfectly certain they were right." Mr. PARTRIDGE'S counsel tried to show that the Council had not properly exercised its powers, that it had acted without sufficient evidence, that even barristers were known to advertise or do something like it (a statement which seemed very much to surprise the eminent judges), that Mr. MACNAMARA, as representative of the College of Surgeons on the Council, was both accuser and judge, and that from all these facts an inference of malice might be drawn. The Court took an entirely different view, and, as we have said, fully justified the methods and the conclusion of the Medical Council.

It is of course true that the decision of the Court of Appeal in this case only applies to the case of a dentist advertising after he has solemnly undertaken not to do so. But all the judges let fall expressions which signified pretty plainly that in their opinion advertising by dentists is a grave offence, to be censured and punished as much as in medical men or in barristers, and decidedly to be punished in these. The Master of the Rolls struck the right note when he said, "No one need become a member of the dental profession unless he desires it. I say the authorities—this domestic tribunal—have a right to determine if it is within reason whether the conduct is or is not disgraceful professional conduct." A man enters a profession for the advantage and respectability implied in the conditions and discipline of its membership. A diploma is the honourable alternative of advertisement. It is the *testamur* of judges as distinguished from personal boasting, in which no real value resides. If a man resolves on the latter method of appealing to the public, he should in justice abandon the former, and he should do it willingly. The public, too, must make up its mind to elect between legitimate practitioners and quacks. It is altogether unreasonable, as we have lately said, that a man should wish for the incompatible advantages of being in a profession and acting as if he were entirely superior to its rules and laws. These rules and laws are made in the interest of the public. And unless they are to be enforced on barristers, solicitors medical men, and dentists, frauds and deception of the most cruel kind will be practised. We maintain that such domestic discipline of professions is eminently needed, and that the Royal College of Surgeons of Ireland and the Medical Council have in this case merited the approval of the entire medical profession, as they have earned that of the Court of Appeal.

LAST week we gave some account of the health administration of the last London County Council, and we referred more particularly to the work which had been undertaken under the Housing of the Working Classes Act. We propose here to discuss briefly the position of the Council in respect of health administration generally, and in doing so it is necessary to point out that until the Public Health (London) Act of 1891 came into force at the beginning of the present year, the Council has had very little, if any, statutory relation with the work of disease prevention in London.

The Local Government Act of 1888, which brought the Council into existence, enabled sanitary authorities within

Digitized by Google

the administrative county to reappoint their medical officers of health under conditions that required the Council to contribute one-half of the salaries of these officers, and these contributions on the part of the Council were the occasion of empowering the Local Government Board to control the appointment and removal of the officers. A certain number of the sanitary authorities availed themselves of this opportunity of reducing local expenditure, but others held aloof; and even those which circumstances required to make new appointments did not always think it desirable to surrender their full control over their officers. One indeed (Shoreditch) thought it well to attach an altogether inadequate salary to a very responsible office, and to pay this trifling salary itself, and thus to escape the protest which both the Local Government Board and the County Council might have made against an arrangement which showed how completely the Shoreditch vestry failed to recognise its responsibilities. Under these circumstances it is very much to the credit of the medical officers of health of the London districts that they have cordially coöperated with the Council's medical officer in regard to the work of observation which the latter has undertaken. Notable instances of this coöperation became known to us during the late Council's tenure of office, and we may cite the speedy suppression of an outbreak of typhus fever, which threatened to assume serious proportions, in south-east London, and the investigation of typhus fever prevalence in London, concerning which the medical officer of the Council recently presented a report to his authorities, as evidence of this coöperation, on which we commented at the time.

The Council's first duty was to communicate to Mr. RITCHIE the amendments of the London Public Health law which it thought to be necessary, and, as evidence of the nature of the Council's work in this matter we may recall to mind the testimony of Mr. RITCHIE when he introduced his Bill into the House of Commons. Thanks to this statesman, a very useful measure has been made operative in London. By the Public Health (London) Act the Council has been put in touch with sanitary administration in all parts of the metropolis. It is impossible for sanitary authorities to make new appointments either of medical officers of health or sanitary inspectors without receiving from the Council one-half of the salaries which they pay. The Commissioners of Sewers have already re-elected their officers, and the Council will therefore in future pay one-half of their salaries. By degrees therefore the influence of the Council is being extended into all parts of the metropolis, and we may assume that in a very short time London, for health purposes, will be united. The Council, moreover, from the beginning of the present year will receive from medical officers of health, not only copies of their annual reports, but of special reports relating to outbreaks of infectious diseases in the several districts, and it may be expected that this knowledge which the Council will possess will prove of considerable value to the metropolis. The Council, too, is empowered to make by-laws for the prevention of nuisances which will enable it to render useful service to the metropolis in making life more comfortable and the conditions of London more wholesome.

But the chief powers which the Council possesses are to be found in two sections of the Act. It is authorised by these to undertake itself any duty which devolves upon sanitary authorities under the Act, and in respect of other matters it may make representation to the Local Government Board, and may be empowered by that Board to exercise any function which primarily is vested in sanitary authorities. It is evidently intended that the Council should watch over all the details of the administration of sanitary authorities, should call attention to any deficiency which may be detrimental to the public, and ensure that lax administration shall no longer continue. Upon the Council and upon its medical officer, therefore, is thrown a great responsibility; but, judged by the work which has already been done, there is no reason to believe the requirements of London will not be fully met.

For the purposes of a complete health administration further legislation is still needed. We noted the other day the demand of the Metropolitan Asylums Board to be created a sanitary authority. Whatever might have been the possibility of endowing the Managers with these powers some years ago, this has become altogether impossible since the Public Health (London) Act was passed. It cannot indeed be long before some of the more important functions of the Managers are transferred to the Council, and we shall gladly see the Council recognising to the full its new responsibilities, so that it may be ready to undertake at a fitting time the larger duties which must devolve upon it.

The London County Council, in respect of the health administration of London, has an immense future before it. It is evidently preparing itself for the proper performance of its duties. It has created a new Health Department, with the medical officer at its head, and it may be expected that the next three years will not pass without leaving its impress upon the sanitation of the metropolis.

THE case of "HANBURY *v.* HANBURY," in which the plea of insanity was put forward as a defence in a divorce suit, is of exceptional interest, in so far as this plea had not previously been urged during the more than thirty years that the Divorce Court had been established. The case was tried before the President (Sir C. BUTT) and a special jury, and the hearing occupied several days before the decision was arrived at on the 17th inst. The circumstances under which the petition was brought were briefly the following. The respondent was a partner in a brewery business, and was married to the petitioner in 1875. They cohabited until 1886, and six children were born of the marriage. They had for some time lived happily together, but by 1883 Mr. HANBURY had taken to indulgence in drink, with the result that he had not only used personal violence, but even threatened to shoot his wife. In 1883 he became a voluntary inmate of an asylum for inebriates on at least two occasions. In 1884 he was placed in a private asylum, under certificates, suffering from acute mania, with delusions. In the same year a petition for separation was compromised, and Mrs. HANBURY'S allowance was raised from £500 to £800 a year; and it may be taken that no question of pecuniary motives entered into the case, as Mrs. HANBURY, on the one hand, not unnaturally sought that due provision should be made for herself and the children; while, on the other, it appeared

Digitized by Google

that Mr. HANBURY had shown every disposition to do what was proper in this respect. In 1886 Mr. HANBURY was again placed in a private asylum, but was discharged after a short time. His wife then finally separated from him. Since that date Mr. HANBURY had been from time to time under restraint as a lunatic, and a brother of the petitioner, who said that in 1880 he first noticed that the respondent had taken to drink, alleged, in cross-examination, that from 1886 to 1889 he had not seen him thoroughly sober during the whole time. Several medical men, including experts in lunacy, who had been consulted or who had had him under their care, gave evidence as to the respondent's mental condition. There is no room to doubt, from this evidence, that he was subject to attacks of recurrent mania accompanied by delusions, and more or less associated with excessive indulgence in drink. These attacks occurred at irregular intervals, and they had the effect of causing Mr. HANBURY to become in turn depressed, wild, excited, abusive, threatening, cruel, and dangerous. The medical testimony was to the effect that the indulgence in drink was the result, or at any rate the concomitant, and not the cause of the insanity—a point which we regard as not by any means clearly established as to the drink question prior to 1883, when the respondent first voluntarily placed himself under control. This reservation is not unimportant when we bear in mind the varying opinions held on this subject in individual cases, and the risks and evils that are apt to result from confused notions as to the respective positions that should be assigned to drink and to insanity in relation to the question of responsibility. At all events, in the case under consideration the outcome of the trial was, in the first instance, to establish the existence of insanity in the respondent, who pleaded that if the acts of cruelty and adultery alleged were committed, he was a lunatic at the time, and not responsible for his actions. It was shown, however, that the insanity was of the recurrent form, with intervening periods of sanity; that he was very intemperate in his habits, and had suffered from delirium tremens; and, further, that when not under the influence of drink he was of a kindly and affectionate nature.

The President, after referring to the painful nature of the case and the amount of sympathy that had been invoked on both sides, went on to say that really the matter must not be one of sympathy one way or the other. There were certain facts to be determined, and a grave and difficult question in this case was as to the effect of insanity as a defence to a suit for dissolution. That, broadly stated in that way, so far as the learned judge was aware, had never been decided in this country, and he did not know whether in its broad aspect it ever would be decided in this country, because there was insanity and insanity, and he could well conceive that there might be cases in which insanity might be a defence to an action for dissolution of the marriage. Having dealt with the evidence as to the cruelty and adultery, which his lordship said was abundant to entitle the wife to the relief she sought, he then came to the plea of insanity. His view on this point was that it must be a lasting and abiding insanity, something distinct from recurrent insanity, and he was not at all satisfied that the plea was a good one. The main object of the Divorce Act, in his opinion, was not so much punishment or retribution for marital offences as protection to the party. His lordship went on to say that, assuming that the acts of violence committed by the respondent were not brought about by intemperance, but were the result of hereditary disease (which, we may remark, was maintained by the medical witnesses), he should still be disposed to hold that acts of cruelty committed in these fits of mania entitled the wife to relief. But in this case, if the wife proceeded under the criminal law against her husband for violence and cruelty, she would be able to get relief from her husband on the plea of insanity by his being dealt with as a criminal lunatic; and, on the footing here urged by the learned judge, it is difficult to see why the plea of insanity (involving irresponsibility) should be operative in one case and not in the other.

His lordship asked the jury to find whether the mania resulted from drink, or whether the drinking resulted from the disease. There was abundant evidence that this man drank heavily and constantly, and it was said that if the drink could not form the excuse, then the disease was hereditary; but no evidence whatever had been offered that any of the ancestors of Mr. HANBURY suffered in the manner which was suggested, while the respondent himself had not elected to give evidence, because it was said it would be dangerous to his health if he did so. This absence of the respondent from the court is one of the weakest and least satisfactory portions of the case, and it testifies to the incomplete, not to say illusory, character of the evidence which may be produced in cases of the sort. For if Mr. HANBURY at the time of the trial was in one of his lucid and happier intervals, his appearance would not support the allegation of insanity; if he were then in a state of mania he might not be in a fit state to do himself justice and to refute charges—possibly unfounded—made against him, or to give any evidence (if he had it) exculpatory of his own conduct under circumstances that were merely suspicious and not proof positive as to guilt. There is no reason for implying that in the HANBURY case all was not carried out in a legitimate and proper manner; but it is sufficient to illustrate the evils and difficulties that arise, or could be made to take effect, where from motives that were either unworthy or not straightforward the question of insanity comes to be mixed up in divorce suits. It is not difficult to conceive of a husband or wife contriving to neglect an insane spouse and bring about adulterous intercourse, and then, in the unavoidable absence of the respondent's evidence, gaining a decree *nisi*. It is to be hoped, therefore, that the plea of insanity will not come to be urged frequently in cases of this sort, as the variations from the normal healthy mental condition of an individual in the direction of eccentricity, drunkenness, and insanity, and in relation to immorality and cruelty, are too ill-defined and too much a matter of individual opinion for any satisfactory general rule to be laid down. We are bound to say that upon the evidence in the case of "HANBURY *v.* HANBURY" we are not surprised that the jury arrived at the verdict that the respondent had committed the acts of cruelty and adultery charged, and that at the time he was capable of appre-

Digitized by Google

ciating their nature and consequences. His lordship pronounced a decree *nisi* for the dissolution of the marriage with costs, and custody of the children; and on application he granted access to the children on behalf of the respondent, subject to arrangement.

IT says much for the widespread interest taken in the deeper problems of pathology that so recondite and difficult a subject as that of the manner in which the organism is rendered insusceptible to the action of specific virus should have attracted such large audiences at the Pathological Society, and that the debate, extending over three sittings, should have been so well sustained. Certainly, the interest in the question was heightened by the quasi-romantic character of the doctrine of phagocytosis, wherein the process of protection resolves itself into an active defence by the living cells of the body against the assaults of the bacterial host; and the knowledge that this doctrine would be as warmly opposed by one section of pathologists as it would be supported by the other doubtless quickened the anxiety to hear both sides of the question set forth. Now that this debate is over, and the advocates of phagocytosis and of chemical protection have expounded their views, it is natural to inquire where we stand. It would be impertinent and cynical to dismiss the question as if nothing at all had been gained by its discussion; or as if all the labour which has been expended in attempts to solve it had left us in as much ignorance with regard to the real problem as before. This is not the fact; but we think it may safely be said that the whole problem has by no means been solved, and that probably Dr. SIMS WOODHEAD is right in his belief that the eventual solution will be found between the two sets of doctrines that have been so skilfully advocated.

Sir GEORGE HUMPHRY, in the remarks with which he closed the debate, did excellent service to the cause of pathological inquiry by pointing out that the matters about which there has been so much debate involve questions which at the present time are practically insoluble; and in illustration thereof he alluded to the known clinical facts of the history of specific fevers, and the lack of explanation—other than the discarded theory of "exhaustion"—of the phenomenon of their sudden subsidence after going through a definite cycle of evolution. Some profound change must have taken place in the organism to produce this self-limitation of the disease, but no experimentalist has been able to prove in what that change consists. So is it with this question of "immunity"; for although Dr. SIDNEY MARTIN urged that by experiment the investigator is in a better position to control circumstances than by the clinical observation of disease, yet between the artificial immunity—or, as Dr. RUFFER more aptly termed it, "resistance"—induced by the experimenter and the natural protection which experience teaches is produced by one attack of a specific fever there is at present no very close relation. Dr. SIMS WOODHEAD, at the commencement of his reply, emphasised this difference by speaking of the animal which had been artificially protected as in no way comparable to one naturally resistant to infection. It is well to bear this in mind in attempting to gauge the importance of researches upon "immunity," and in endeavouring to determine in what manner the resistance to viruses is brought about. But it is also well to recognise that the special question contained in the latter problem is not capable of a limited or narrow treatment. Indeed, from the wealth of facts furnished by the numerous speakers in this debate, it is clear that the subject is beset on all sides with matters which require the profoundest study. To attempt anything like an adequate analysis of this discussion would far transcend the limits now at our disposal, and we must perforce be content to discuss only the main issues at stake, although fully conscious of the imperfections of such a mode of regarding the matter. Thus, then, we have on the one hand an explanation of the resistance opposed to infective disease—or, more strictly speaking, to pathogenic microbes—in the active antagonism of the amœboid cells of the body, the transference of the normal property of phagocytosis, which plays so useful and necessary a part in nutrition, to the special property of active destruction of microbes. On the other hand, it is contended that this bactericidal property is an attribute of the fluids of the body as distinguished from the cells; and the presence of bacteria within cells is explained either as being in accordance with the ordinary functions of leucocytes, such as their ingestion of any foreign particles, or as evidence that the bacteria themselves are the aggressive parties, and that it is they which consume the phagocytes and not the converse.

When, however, we regard the question as one between the operation of the living cells and of the fluids of the body, we cannot but agree with Sir G. HUMPHRY and Dr. W. HUNTER that the distinction is more artificial than real. The day has passed for maintaining a strictly humoral as opposed to a solidist theory of pathology. Physiology teaches that cells and fluids in the living body are essentially interdependent, and that ultimately cell-protoplasm is the centre whence all the vital and chemical actions of the organism flow. Nor can we suppose that this is gainsaid by any who take what has been called the "humoral" side in the present controversy, only they seem to imply that certain constituents of the blood, or, more correctly speaking, certain materials which can be extracted from the blood (and of which there is no proof that they exist as such in the living body), possesses the power of antagonising the action of bacteria or of neutralising their virulent products. Animals which are not naturally insusceptible to such external viruses, it is averred, may become so artificially by the introduction into the blood of "antitoxines"—products, it may be, of the self-same bacteria formed in the process of their cultivation in suitable media. This is, we are aware, but a bald statement of the substance of the "humoral" position, which has received so much support from fact and argument at the hands of numberless investigators both in this country and abroad. During the recent debate these arguments were concisely stated by Drs. KANTHACK and MARTIN and Mr. HANKIN. On the other hand, phagocytosis, apart from the microscopical evidence adduced in its favour, has the merit of being a more tangible and material doctrine; and there is something singu-

Digitized by Google

larly attractive about the details of the process in respect to the question of protection and insusceptibility, whether natural or artificial, that may bias the mind in its favour. It is the outcome of a series of observations which abound in interest, and which bring into close connexion normal and pathological processes with a deftness that is to be admired. The action of certain substances in attracting amœboid cells and that of others in repelling them, as shown by a series of beautiful experiments, has been drawn into the subject, although the crucial difficulty alluded to by Professor BURDON-SANDERSON in the matter is that it entails the acceptance of some specific powers not possessed by the leucocyte in its ordinary state. The remarks of Drs. WRIGHT and ADAMI, as well as those of Dr. HUNTER and Dr. SIMS WOODHEAD, seem to imply that it is possible to accept the essential principles of both views of the production of "immunity," chemical or humoral changes being then considered as supplying the phagocytes with the specific power of resisting the inroads of specific organisms. In Dr. RUFFER'S exposition we have the doctrine of phagocytosis in respect to this question clearly enunciated, and those who read his paper will be fortified with the strongest reasons for accepting it, so far as it is intended to be accepted, in place of a more subtle doctrine of chemical protection.

The debate, it will have been noticed, was mainly in the hands of the experimental school of pathology, a school, which, as the President pointed out, has done much in this country in spite of disadvantageous circumstances. But the question could not have been fully considered had there been no reference to clinical knowledge, and the contribution of Dr. BRISTOWE as well as the remarks of Sir G. HUMPHRY were especially interesting in this regard. Viewed from this aspect, it is apparent that there are several matters in the history of specific diseases that require elucidation at the hands of the bacteriologist; these are of almost equal importance with the more obscure question of "immunity"; such, for instance, as the affinity of certain viruses for special tissues of the body, the varying types of fever that accompany the diseases, the singular fact of critical defervescence in several of these affections, and the possibility of aborting specific fevers by treatment. These and similar topics need to be studied anew in the light of modern research. Therapeutically, the doctrine of phagocytosis may be thought to receive support in the fact that the most efficacious way of meeting the inroads of infective disease is by using every means to fortify the vital powers of resistance against the invader.

THE Medical Society of the State of New York received, on Feb. 3rd last, a report from a special committee, consisting of Dr. A. JACOBI, Dr. W. C. WEY, and Dr. B. F. SHERMAN, on capital punishment. There can be little doubt that the Society has been led, however imperceptibly, to the production of this report by what has lately been enacted near them in carrying out the extreme sentence of the law. But this is not the subject labour of the committee; the committee appears to have laid itself out to study, from the medical side alone, the question of capital punishment. All reference to metaphysical questions is avoided. The members of the committee felt that to ventilate the question of capital punishment, its perpetuation or abolition, and the subjects connected therewith—viz., the nature of crime, of responsibility or irresponsibility, of the cerebral functions called judgment and will, the existence or non-existence of a free will and its limitations, from any other than an anatomical and physiological point of view—that is, a strictly scientific point of view—would not be the correct method for them to follow. Most wisely, therefore, they confined themselves to the consideration of a subject in which trained thinkers on questions medical would feel the deepest interest, and in which they as trained thinkers would be most useful in advising and guiding a nation at large.

From this standpoint the reporters deliver their judgment. "Crime is an evil impulse that ought to be controlled. The controlling powers are the cerebral functions of judgment and will." This is the only general proposition they offer. They proceed thence on physical argument. "Whoever is held responsible for his aberrations and his wrongdoings is termed and punished as a criminal." But "Whoever is considered irresponsible is no longer a criminal to be punished, but a lunatic against whose vagaries society takes pains to protect itself." So amongst civilised peoples both the punishment of the criminal and the incarceration of the hopelessly insane are, or ought to be, but different modes of self-preservation. By truly civilised men they say "the theory of revenge or retaliation has been given up long ago. Their minds are more bent upon the preservation of the physical and moral health of the community than on the spiteful annihilation of the rebel against the common welfare."

The reporters proceed to argue with great skill that the boundary lines between responsibility and irresponsibility are uncertain boundary lines, and they point out that many of the physical changes which lead, or can lead, to criminality may be preventable, and may be due to no fault of the criminal in so far as their first starting forth is concerned. The servant girl who lets a baby fall may maim it for life, or may so affect its brain as to change the current of its thoughts and feelings into criminality. The development of a syphilitic infant into either a healthy man or an invalid, or the development of the luckless possessor of a cerebral endarteritis or gumma, with their physical or moral consequences, into a healthy man or an invalid, may depend on the diagnostic knowledge and therapeutical skill of a practitioner of medicine. The injudicious use of forceps—to which might well and wisely be added the judicious and skilful but necessary use of the same instruments, or the injudicious avoidance of their use in some cases of prolonged labour from contracted pelvis; the influence of disease and conditions of the heart and circulation on the brain and the cerebral functions; the diffuse affections of the brain from various physical causes; and, above all, that inanition of brain which springs from overwork and anxiety, are adduced as common causes of aberrations with which medical men are conversant from their daily observations of mankind, and which account for very much of what the ordinary and even the judicial mind designates as crime and visits with punishment, sometimes, it would seem, on the principle of retalia-

Digitized by Google

tion. The reporters add, "the symptoms of most of these conditions may resemble each other very much; delirium, mania of all kinds—mainly persecution mania—puerility, irascibility, diffidence, misanthropy, are just so many symptoms of acute, subacute, and chronic forms of disease. Epilepsy is a frequent cause of outbreaks of excessive violence. At this moment a negro is on trial for murder. He is known to have severe attacks of epilepsy. Experts have sworn he is a criminal. Experts have sworn he is diseased and not responsible. What does it teach? It teaches that there is surely reason for a doubt as to the causation of the criminal act. It should also teach that society, as represented by the jury, and as represented by the humane spirit of the times, ought to keep a sharp look-out on its own dignity. A man may blunder, but society cannot afford to be brutally mistaken where it is at the same time accuser, judge, jury, and executioner."

The concluding part of the report to which we have thus directed attention is as follows: "This Medical Society of the State of New York, having the advantage of physiological knowledge, and being aware of the difficulties of being always correct, and of the absolute impossibility of making a positively safe diagnosis in every case of alleged crime or presumable cerebral disease or anomaly, expresses its opposition to the perpetuation of capital punishment and its hope that means will be found to protect the community by less uncertain and less inhumane methods."

Whilst by no means prepared to express our own concurrence with the above forcibly propounded opinion that capital punishment should be abolished, we cannot withhold our admiration of the humane impulses which have prompted and the scientific spirit which has directed the Medical Society of the State of New York in their report on a matter of supreme interest and importance to the people and the Government of every civilised community.

Annotations.

"Ne quid nimis."

THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

THE announcement that Dr. Buchanan, F.R.S., has intimated his intention to resign the post of medical officer to the Local Government Board at the end of the present month will be received with some surprise by those who, knowing the unremitting attention he has bestowed on his official duties up to the last moment, are able to appreciate the exceptional abilities which he renders and has all along devoted to the public service. His career, first as a London physician who devoted himself particularly to the study of the continued fevers, next as a temporary inspector under the Privy Council, and finally as medical head of the Public Health Department of the State, has been throughout one of great distinction; and we have only to refer to the able contributions which he made to Sir John Simon's former reports to the Privy Council, and next to his own annual reports to the Local Government Board, to recall a series of public health literature which we believe to be unique in value and importance whether in the English or other tongues. Dr. Buchanan received the Fellowship of the Royal Society many years ago, he is now sitting on the Royal Commission on Tuberculosis and the Nomenclature Committee of the Royal College of Physicians, he is also a member of the Senate of the University of London; and he therefore lacks no means for bringing his matured experience and advice to bear upon those branches of science in which he has so long taken, and still takes, such active interest. His loss will, we are sure, be much felt by his colleagues in the Medical Department, who have always considered that in their chief they had a staunch friend and counsellor.

THE LOADING OF MERCHANT SHIPS.

A BILL to amend the law relating to the loading and provisioning of merchant ships has been introduced into Parliament, and is influentially supported not only within the House, but also without, since it is strongly advocated by Mr. Plimsoll. With its aims most people will sympathise, especially when it is borne in mind that, so far as loading is concerned, the existing provisions of the law have proved wholly inadequate. The Cardiff magistrate recently, when inflicting the maximum fine in three cases of overloading, took occasion to remark that such fines as he could inflict were no punishment, because in many overloading cases the freights earned by excessive loading were greater than the fines, so that when these latter had been paid there remained a balance to the credit of the overloading. The present Bill proposes to deal with this difficulty, not by the imposition of a larger fine, but by the simple expedient of authorising the Customs officer, or "other prescribed authority," to withhold the clearance papers of the overloaded ship until the necessary lightening is effected. This remedy, if proper officers are employed in the discharge of the duty and due vigilance is exercised, will be much more satisfactory in every way than the present system, and will have the double advantage of being milder in form and more effective in operation. The other subject dealt with in the Bill is the inspection of food stores, and substantially the proposal is to dispense with the complaint by the crew now necessary to give jurisdiction to the officers authorised to inspect, and to provide for systematic inspection by a "prescribed officer" of all ship's stores of food before clearance. It is very difficult to form any notion how such a change in procedure would work. It might result, as it is intended to result, in a more effective supervision than is at present exercised. On the other hand, it might relegate the whole subject to a region of routine in which systematic inspection would mean an inspection systematically bad. The importance of securing fit and sufficient supplies of food for the sailor cannot be overstated, and we wish the highest success to those who have interested themselves in the most excellent objects to which this Bill is directed.

TOBACCO AND DEPOPULATION.

THOUGHTFUL Frenchmen, it is well known, are coming to regard with some uneasiness the signs of stagnation, if not of actual decrease, in the population of their country. Malthusian doctrines, however attractive in point of economy, do not now appear to exercise that fascination which once was theirs, and which we cannot doubt has much to do with the reduction of reproductive energy. We are reminded, however, by the author of a paper on this subject recently published, that other causes may have contributed somewhat to the same result. Under the heading of "Le Tabac et la Depopulation de la France" M. E. Decroix, who is the founder of a Society intended to check the abuse of tobacco, assures us that, among such, a prominent place must be assigned to the influence of tobacco. The arguments by

Digitized by Google

which he seeks to fortify this opinion are by no means void of ingenuity, and are supported by the evidence of investigations and information contributed by various medical men, and of the vital statistics afforded by different departments of the country. Among the former there seems to be a consensus of opinion that tobacco consumed in excess exhibits in various degrees a constant sedative influence upon the reproductive system. A series of experiments by Dr. Depierras are quoted in order to show that the same rule holds good among the lower animals. In this case the offspring of cocks and male rabbits exposed to the fumes of tobacco are said to have proved feebler and shorter-lived than those born under natural conditions. The conclusions founded upon statistical testimony are very emphatic, more so, indeed, than we should consider to be justified by the accuracy of the method pursued in this inquiry. After comparing ten departments in which a greater, with ten others in which a less, amount of tobacco is consumed, M. Decroix, by summing up their collective disparities, has no difficulty in showing that in the former there is a marked excess of deaths, of stillbirths, of divorces, of illegitimacy, which he takes to be a mark of morbid vitality, and a falling off in the size of families. When, however, we compare the departments with each other separately, we frequently miss that evident connexion between cause and effect which the author's views on tobacco would lead us to expect, and it is clear that we must in many cases allow for the action of other influences in producing the result for which it is blamed. Under the circumstances we cannot agree with all the propositions advanced in this paper. At the same time it cannot be denied that the excessive use of "the fragrant weed" is to be numbered among the forces opposed to a continuance of healthy life.

THE INSANITARY CONDITION OF BARRACKS.

IT was not to be expected that Lord Wolseley's recent statement strongly condemnatory of the condition of many barracks in England and Ireland would pass unnoticed, and Mr. Hanbury called attention to it in the House last Monday. His lordship is reported to have said that he could point to many barracks which were a crying disgrace to the nation; but they were used year after year, although they were known to be abominable habitations for human beings. Notwithstanding that the fact had been reported for the last fifty years, nothing had been done except by the present Government, who had done a little. Mr. Hanbury wanted to know from the Secretary for War whether he could specify, or would call upon Lord Wolseley to specify, the particular barracks referred to, and whether this state of things would be entirely removed by the large amount now being expended on barracks, and if so, within what period of time. Mr. Stanhope replied that, as regards barracks generally, he had given full information to the House, both as to the urgent cases requiring attention and the work being done, but the sum at his disposal would not suffice to rebuild all the barracks; and, in further reply to Mr. Hanbury, he said that the barracks which were admitted to be insanitary were being put into repair, and that troops would not be put into them until this was done. It must be admitted, we think, by anyone who will compare the buildings, whether barracks or hospitals, that have been erected of late years with those which were in existence fifty years ago that there has been an immense change for the better, and every year more attention seems to be devoted to providing for the health and comfort of the soldier. But this does not really touch the question as to whether there are not many old barracks of such a character and construction that they are quite behind the sanitary requirements of the age in which we live. Attempts have been made from time to time to improve them, but it is questionable whether in some instances these attempts have been, or are likely to be, successful or worth the outlay. The most satisfactory and successful efforts will be made in another direction—viz., in the provision of new barracks as a substitute for buildings of an old and radically bad construction. This takes time, no doubt, but it is, nevertheless, the direction in which army sanitarians should move.

THE TEETH OF SCHOOL CHILDREN.

THE first report of the committee appointed by the representative board of the British Dental Association to conduct a collective investigation as to the condition of the teeth of school children was presented at the last meeting of that Society, some comments upon which appeared in our columns. The committee was convinced "that if more attention were paid to the teeth of children the general sum of public health and well-being would be materially increased, inasmuch as the disastrous effects frequently produced, even in early adult life, by the decay and loss of teeth may, in a very large majority of cases, be traced to disease of those organs in childhood." A further contribution on this subject is a paper by Mr. Denison Pedley and Mr. Sydney Spokes, after an examination of over 900 children at the Hanwell district school, in which they state their opinion that the lamentable state of the teeth from caries ought to be combated by systematic treatment by a qualified dental surgeon appointed to such institutions, and in their report they bring forward many sound suggestions. With regard to the temporary teeth, it is popularly believed that they are not deserving of any particular attention, as in the natural course of events they must give place to others of the permanent set. Whilst there may be some ground for this view, it is nevertheless true that much misery to children, as well as detriment to health, can be avoided by intelligently watching and treating temporary teeth. Between the age of six and seven the first permanent molars appear, and are only too often mistaken as belonging to the temporary set, and these most important teeth are allowed to decay without any effort to save them. Irregularity, which is one of the great predisposing causes of decay, can often be remedied by the removal of certain teeth or by the application of some mechanical apparatus.

DEATH BY FALLING.

OF late years a considerable, and perhaps a disproportionate, amount of attention has been devoted to the scientific explanation of the state of unconsciousness. The public, as well as the professional, mind has been treated *ad nauseam* to discussions on hypnotism. The relations of trance and sleep to each other and to various phases of disease have elicited their share of logical ingenuity and of research. Quite lately again an allied condition—that of the numbed sensation consequent upon shock, such as that experienced in falling from a height—has attracted attention, though beyond the assurances of some who have survived this experience that dread and pain are alike absent we have no certain proof of the existence or the essential character of this merciful torpor. According to Professor Heim of Zurich, who has devoted much time and thought to the investigation of the subject, the sensations at such a time of the sufferer, if so he can be termed, resemble somewhat those of drowning persons. In place of pain there is a process of rapid and involuntary mental activity, succeeded by stupor; series of old memories fly past the mind like scenes in some rapid vision, and life is revised, as it were, on the threshold of death. One is naturally tempted to inquire what is the explanation of this extraordinary state, in which

Digitized by Google

the final catastrophe appears to be lost in the dream-slumber preceding it. The preoccupation of rapid cerebration, a species of shock in itself, might furnish a clue to the mystery—at all events, as regards the abolition of pain and fear. We cannot help thinking, however, that other causes must be operating along with this, which at first presents itself as the most obvious. The analogy afforded by drowning is, to our mind, especially suggestive. We may remark that here we have to do with a highly probable alterative of normal brain function in the stimulant-sedative influence of a disturbed circulation. The advent of asphyxia implies the turgescence of all venous channels and capillaries, and the increasing accumulation in these of carbonic acid. It appears to us that the same process must occur in falling. As a rule the fall takes place with head downwards. At the same time there is exerted upon the respiratory passages the suction force of the outer air in rapid transit, acting, we may conclude, in much the same manner as water in a large tube which draws into its own volume the fluid contents of any small communicating channel. Thus it would seem at least a reasonable hypothesis that the coma of death in the circumstances referred to, like the same condition in various forms of disease, is essentially a process of deoxidation of tissue with accumulation of carbonic acid.

THE CASE OF SURGEON-MAJOR W. H. BRIGGS.

IT is a source of sincere gratification to us that attention was called in the House of Commons on the 22nd inst. to the case of this medical officer. Dr. Farquharson asked the Secretary of War whether he had further considered the case with a view to Surgeon-Major Briggs being reinstated in the position which he would now occupy in the service if he had not left it; and Mr. Stanhope, in very handsome terms, replied that Surgeon-Major Briggs would be restored to the seniority he held before retirement. It is well known that this officer rendered excellent service in the department, that he did good and skilful professional work in the field, and that he acted, under very trying circumstances, in a chivalric and honourable way. We heartily congratulate him on the result But what we want to know is, who was responsible for the action that was taken in the matter Why was he called upon to resign in the first instance, and how did it happen that his restoration to the service was coupled with conditions that he could not accept, and which, it seems evident from the War Minister's statement, should not have been made?

HEREDITARY SPASTIC PARAPLEGIA.

IN the last number of the St. Bartholomew's Hospital Reports Dr. Howard H. Tooth puts on record four cases which he thinks come into this category. The name is that given by Dr. Gee a few years ago to three cases of spastic paraplegia in members of the same family—viz., father, son, and daughter—which he observed and recorded. Of Dr. Tooth's cases two occurred in one family and two in another. In the first pair of brothers the onset of symptoms took place at the age of fifteen, and in one it was preceded by an injury to one hand. The history of the advance of the disease was similar in the two—viz., weakness of the back, stiffness of the legs, speech stammering at first, latterly becoming inebriate in character, extensor rigidity in both legs, with exaggerated knee-jerks and an absence of pains, ocular symptoms and ataxy. In one case there was slight incontinence of urine, and in the other a marked condition of pes cavus. Of the second two brothers the history differs in no important point, except that the onset of the symptoms was earlier, and there seemed to be more general weakness. The cases, as Dr. Tooth points out, present the clinical picture of lateral sclerosis. This was not secondary to cortical disease, as was evidenced by the absence of convulsion and of mental deficiency, and by the fact that the patients were not affected from birth, but were in two of the cases healthy up to fifteen years of age. Nor can the symptoms be accounted for by a local transverse lesion; because, apart from the improbability of such a condition appearing in two members of the same family at the same age, there is no evidence of disturbed sensibility. It certainly seems, as Dr. Tooth says, that those cases exhibit a clinical condition very closely analogous to Friedreich's ataxy, but differing in some important respects. In those cases the bulk of the degeneration, so far as we are able to judge of pathological anatomy from clinical phenomena, appears to fall upon the lateral columns, instead of, as in Friedreich's disease, on the posterior; and so, instead of ataxy with absent knee-jerks, we find rigidity with exaggerated reflexes. The two classes resemble each other in showing an absence of pupil symptoms; for in Friedreich's disease the pupil seldom, if ever, shows the absence of light reaction, which is so frequent in ordinary tabes.

ENDOWMENT OF ORIGINAL RESEARCH.

A GENTLEMAN has, we are informed, established a scholarship of £100, tenable for one year, for the encouragement of original research. The scholar will be selected by a committee composed of Dr. George Thin, Surgeon-General Cornish, and Professor A. Wynter Blyth. The conditions of the scholarship are that the research shall be in a subject requiring for its elucidation both chemical and bacteriological methods, and the subject will be selected by the committee of selection with the concurrence of the scholar. The work is to be done in the laboratories of the College of State Medicine, 101, Great Russell-street, W.C., and the scholar will have to devote his whole time to the work. Applications should be made by letter addressed to Surgeon-General Cornish, College of State Medicine, 101, Great Russell-street, W.C., on or before April 18th, 1892.

EXPERIMENTS WITH CELLULOID.

A CORRESPONDENT recently forwarded us three varieties of articles made from the material known as celluloid—viz., an imitation ivory dice-box, an imitation tortoiseshell hairpin, and a variegated pattern of a toy bouncing ball. In view of the possible dangers arising from the use of buttons, hairpins, &c., made of this material, we have submitted the above to experiment, and the results are perhaps of sufficient interest to justify record. The articles were, without exception, highly inflammable. On applying a light they burst instantly into a brilliant smoky flame like that produced when camphor is ignited. It was not difficult to blow the flame out, but dense fumes continued to be given off which were quite as inflammable as coal gas, and, on placing a light in the stream of smoke at a distance of six inches above the material, a bright flame instantly ran down and re-ignited the article. Portions of the three articles were next placed on paper at a distance of eighteen inches, in front of a red-hot fire, where the temperature was ascertained to be 100° C. (212° F.). Beyond the softening of all the pieces, and a slight swelling of the tortoiseshell and toy ball sections, no signs of ignition could be observed. The paper on which the articles were resting was then placed at about twelve inches from the fire, where the thermometer showed a constant temperature of 110° C. (230° F.)—i.e., ten degrees above boiling point. In ten minutes the pieces of thin celluloid, of which the ball was composed, swelled out, emitted dense fumes of camphor, and charred, without, however, showing any sign of flame, while the paper was only blackened and scorched. In fifteen minutes precisely a similar occurrence happened

Digitized by Google

to the hairpin, the imitation ivory being as yet unchanged. Another hairpin and a fresh piece of the toy ball were then placed along with the yet unfired ivory specimen within six inches of the fire. The piece of toy consumed rapidly away in little over a minute, apparently without flame, and the hairpin followed suit in about three minutes. The paper upon which they lay was charred only, not actually ignited. The imitation ivory showed slight swelling under these conditions, but not until the temperature was raised to 145° C. did it puff up and give off abundant smoky fumes of camphor, as in the previous experiments. In no case could it be said that the combustion was accompanied by flame, nor was the paper upon which the articles were resting actually ignited; it was only scorched and charred. The difference exhibited by the ivory specimen in susceptibility to the influence of heat may possibly be accounted for by the fact that, first, it is more dense, and, secondly, it contains a fair amount of zinc salt. On ignition the ash was found to consist almost entirely of zinc oxide. The addition of this metallic salt serves probably to make transparent celluloid opaque and to give it the appearance of ivory. The tortoiseshell pins contained no zinc, and yielded very little ash at all; and while in the toy ball, which was of a variegated pattern, the white opaque spots contained the metal, none was found in the clear portion of the material. All the specimens emitted a strong odour of camphor on rubbing, and more especially the tortoiseshell and transparent variety. Ether also dissolved out camphor from each of the specimens. It would appear from these experiments that celluloid is, generally speaking, not so dangerous as might be supposed, although, in view of the testimony recently furnished by Professor Boys, F.R.S., of the inflammability of buttons made of this material, there are exceptions; but probably these exceptions depend upon a variation in the composition of the celluloid, some preparations, perhaps, containing more pyroxylin, and accordingly less camphor, than others. The manufacturers of celluloid would in any case do well to give their attention to this matter, and by adopting a process which will secure greater certainty in the composition and character of this beautiful material, or by incorporating with it some substance which will render it practically non-inflammable, rid it of the one quality which at present would seem to render its general use not quite safe.

DEATHS UNDER CHLOROFORM.

A DEATH under chloroform occurred at University College Hospital on Wednesday, March 9th. The patient, a young man of twenty-two, suffered from old-standing jaw mischief, and it was proposed to remove some dead bone. Chloroform was carefully given upon lint, and no unusual symptoms occurred until, as the operation was being commenced, the gouge being placed in the carious bone, respiration and the heart's action stopped. The operation was discontinued; the tongue was drawn out of the mouth, and artificial respiration was at once commenced and maintained for a considerable time. Several natural respirations occurred, and care was taken to synchronise the artificial with the natural breathings, but no pulse or heart's movements could be detected. There was free entry of air into the lungs all along, and no delay occurred before restorative measures were commenced. Various efforts to restore the heart's action were made—Nélaton's inversion, nitrite of amyl inhalation, ice in rectum, and stimulation of precordial area, &c.,—but to no purpose. The post-mortem examination showed that the lungs were a little emphysematous, and some old adhesions existed. The heart was hypertrophied, with rather marked thickening of the coronary valves, but no vegetations, and the columnæ carneæ were hypertrophied. In this case careful note was taken throughout, and it was strikingly manifest that no respiratory or cardiac weakening occurred before the final and absolutely sudden extinction of life. There was no overdose in the ordinary sense of the term; indeed, no chloroform was being given at the moment, and yet there was, on the other hand, complete narcosis. The pathological condition of the organs was insufficient to throw any light upon the death, so the eye-witnesses were compelled to accept the fatality as an instance of cardiac syncope due to the action of chloroform. Some of the chloroform employed had been used for other patients without any ill effects having occurred. Another death occurred from chloroform on March 14th at the General Hospital, Birmingham. The patient, a man aged thirty-eight, suffered from an "internal gathering." He was chloroformed by a senior student with a view to operation—the second, he having passed successfully through one some time before. After four minutes breathing ceased and was not restored, although remedial measures were at once adopted. Ether was not given in this case because the bronchial tubes were slightly affected. The coroner's jury found that the deceased died from heart failure. We have not sufficient evidence before us to comment at length upon the case, but it cannot but strike the reader that if ether were really contraindicated by the state of the patient's lungs, it was a pity the anæsthetist did not use the A.C.E. mixture—certainly a safer anæsthetic than chloroform.

INFLUENZA IN LONDON.

CASES of influenza are still occurring in the metropolis, and indeed during the past week there was a slight increase in the number of deaths attributed to it over those recorded in the preceding week. Thus the Registrar-General reports that the deaths "primarily attributed to influenza, which had been 61, 34, and 30 in the preceding three weeks, were 35 last week," and the cases in which influenza was noted as a secondary cause rose from 5 to 9.

THE OPIUM TRAFFIC: FOR AND AGAINST.

THE responsibility of the Indian Government for the evils associated with the consumption of opium in the East has never been—and, indeed, under present conditions, cannot be—entirely repudiated. It would be remarkable, nevertheless, if the monopoly which it possesses in the production and sale of this drug were wholly incapable of defensive argument. We need not be surprised, therefore, to find that it can rely upon the support of not a few experienced advocates, men of intelligence and judgment, for its justification in this matter. In the opinion of these gentlemen, among whom we may number a recent correspondent, the dangers and the degradation of moderate opium-taking have been exaggerated by anti-opium agitators. Its beneficial qualities as a sedative of the vaso-motor system and a febrifuge, it is argued, have, on the other hand, been ignored, whereas they should at least suffice to justify its moderate and common use, which is as excusable as that of alcohol. We have already discussed these arguments, and it was but very recently (March 5th) that we protested against the view that the therapeutic value of this purely medicinal agent should be accepted as excusing its regular and practically unguarded consumption. Whatever may be said in favour of this practice, opium still remains essentially a poison, and a powerful one. As such, it should not be openly committed to the hands of any or everyone. Its regular use, however moderate, is altogether unnatural. We are unable to see how, even amid the conditions of tropical life, this can ever be justified, except in the treatment of disease and under medical supervision. It con-

Digitized by Google

stitutes no valid excuse for the opium habit to say that the same freedom should be allowed for its indulgence as in the case of alcohol. The position of the two agents is by no means identical. Alcohol doubtless is in its pure state a poison. As commonly sold it is quite a different substance. Disastrous as its effects have often proved—and we would not for a moment defend its abuse—it still remains the less potent drug and the lesser of two evils. As matters now stand, its privilege of sale is already too freely allowed, and an argument founded on comparison should, in our opinion, rather claim its restriction than the liberation of the rival narcotic. It has been asserted that if opium-taking be suppressed in the East the trade in liquor will grow in proportion. We do not believe that this result is inevitable. It is not probable that either evil, if resolutely met, will be found impossible of regulation.

LEGISLATION AND HABITUAL DRUNKARDS.

THE Lord Chancellor on Monday night, in reply to Lord Herschell, said that the Secretary of State was about to proceed immediately with the appointment of a departmental committee to inquire into the best mode of dealing with habitual drunkards. The subject is one of immense importance, and its importance is only equalled by its difficulty. The present legislation inspires no respect, and is practically ineffective. It requires the consent of the drunkard to his compulsory detention in a retreat—a consent which is not likely to be forthcoming in the most fit cases. We do not advocate legislation that would favour the premature interference of law and its representatives with drunkards. It is always right to leave the natural friends and guardians of an habitual drunkard to exhaust their endeavours to save him before invoking any such interference. But there are thousands of cases in which power of interference should be given. In some instances the friends of such patients are driven to foreign lands where the law is more effective.

BURIAL REFORM AND PATENT COFFINS.

WE have been favoured with a view of a specimen of the new coffin patented by the Patent Enclosed Sanitary Coffin Company, of 40, Great Tower-street, E.C. It certainly possesses some advantages, being of oblong form, with square-shaped ends and sides, thus differing from the ordinary shape of coffins in common use, which is supposed to be repulsive to many persons. To these the new shape will commend itself, though we fear that to many others the new shape will be equally, if not more, repulsive. Inside the coffin are four pieces of wood fitted, so as to enclose a space, of the usual coffin shape, to receive the body, leaving at the head and feet four spaces for disinfectants or flowers. The bottom is covered with laths, leaving interstices for charcoal or other disinfectant, and it is claimed for these coffins that they supply all the purposes of burial reform at a greatly decreased cost. It is ungracious to criticise well-meaning reforms, but truth compels us to say that this, like other coffins, has the demerit of dealing only, so far as the sanitary aspect is concerned, with the question of disinfectants. If disinfectants are required at all—and they will be very frequently required if burial be deferred, as it generally is, till the third, fourth, or even fifth day after death—charcoal must be employed abundantly both above and beneath. There must be a substantial bed of the disinfectant below as well as a complete layer of it all over the upper surface of the body, or the object for which the charcoal or other disinfectant is used will not be gained. Medical practitioners will remember cases even in this country where it has been advisable to place the body in the coffin within a very few hours after death, and its closure within twenty-four hours or even earlier has been imperative. It is obvious that in such cases only a most liberal amount of disinfectant will have any effect. This new coffin is one of several which have been proposed. Mr. Seymour Haden proposed wicker coffins, which, however, have not found much favour. The earth-to-earth coffins of the London Necropolis have much to recommend them, especially if, when the patent has expired, their cost should be less. It is very satisfactory to see that so much is being done with reference to this matter of the coffin, which is, indeed, now the real feature of burial reform. We may remind all who labour in this cause that even all through the long period which elapsed while bodies were buried under churches, in vaults, catacombs, bricked graves, &c., burial reform was quietly practised in many an English village. There the burials were few, numbering twenty or less each year, the undertaker was the village joiner, the coffin a few boards nailed together, and the grave a hole dug in the churchyard. The results have been that though these ancient burial places have been used for centuries, there is still unbroken ground left, while the ground already used will continue to receive with all safety fresh tenants. What is required now is to make our cemeteries as similar as is possible to our old churchyards. Mr. Seymour Haden has shown that wood is undesirable as a material for coffins, being not sufficiently perishable in our English soils. He has been amply confirmed by other observers, and, as has been frequently pointed out, the burial service makes no mention of a coffin, but uses the word "corpse" or "body." Instead of the twenty bodies buried in the village churchyard we have to find burial space for, it may be, seven thousand bodies in a cemetery. Hence the importance of the most perishable coffin and the most suitable soil. For our own part, we should not object to see the sailor's "hammock" brought into use on shore, seeing what a neat and perfectly satisfactory coffin it makes at sea. Till that is done we must confess to a preference for that form of coffin which is most perishable—i.e., the coffins of compressed pulp as used in the Necropolis of Woking.

MUSCULAR DYSTROPHY.

To the opening numbers of the new *Deutsche Zeitschrift für Nervenheilkunde* Erb contributes the most exhaustive monograph that has yet appeared upon this subject.[1] The clinical types of dystrophies generally recognised are, first, the "juvenile" form of Erb, beginning in youth, occurring in families, affecting primarily the muscles of the shoulder and upper arm, and often associated with true or false hypertrophy; secondly, the ordinary pseudo-hypertrophy; thirdly, the "infantile" facio-scapulo-humeral type of Duchenne, recently described by Landouzy and Dejérine; and, lastly, the "hereditary" form of Leyden, beginning usually in the legs. Erb has collected nearly ninety cases, and a number of necropsies and reports of examination of excised muscles. He maintains the essential unity of these four forms. In the juvenile and infantile forms there is often pseudo-hypertrophy; in pseudo-hypertrophy there is often atrophy of the shoulder muscles; in both forms the face may be subsequently involved. All forms may be hereditary, and in the hereditary form the shoulder muscles may be involved. All forms agree in the characteristic attitude of the patient, the affection of certain muscles, the occurrence of hypertrophy and pseudo-hypertrophy, the absence of fibrillary twitchings, and the simple quantitative diminution of electrical irritability. One or two cases are reported in which there was reaction of degeneration, but Erb himself has never seen it. Furthermore, transition forms are not uncommon; in the juvenile form the face may be subsequently involved, as it may in pseudo-hypertrophy; the

[1] Abstract in the Boston Medical and Surgical Journal, Jan. 28th, 1892

Digitized by Google

infantile form may show "juvenile" localisation or pseudo-hypertrophy; pseudo-hypertrophy may have later a juvenile localisation, and all may be hereditary. Finally, forms may occur which cannot easily be assigned to any one of these four types. Another argument in favour of unity is that in one and the same family several of these types may be found. From the harmony in all the essential clinical features and from the occurrence of transition forms in the same family, Erb concludes that clinically these four forms are essentially one. On the pathological side Erb has collected the records of eighteen necropsies and twenty-three examinations of excised muscles. He finds the following characteristic changes: Hypertrophy of the muscular fibre, present in post-mortem examinations as well as in the excised portions, and therefore not due, as Oppenheim and Siemerling have claimed, to the results of excision; atrophy of fibres; alteration in the shape of the fibre, which loses its angles and becomes rounded; an increase of nuclei, with the presence of nuclei in the centre of fibres; a fissuring and division of the fibres and the formation of vacuoles. These changes occur in various combinations, but it is impossible to make any anatomical distinction between the four forms. In all, for instance, hypertrophy and fissuring may be rare or frequent, and the fibres may be equal or may vary greatly in size. The interstitial tissue is usually increased in amount, and a deposit of fat is common in it. In general, this proliferation of connective tissue and fatty infiltration are pronounced in pseudo-hypertrophy; but it is also observed in the other forms, and some of the muscles in pseudo-hypertrophy show it only in a slight degree. The complete necropsies show, as a rule, that the nervous system is intact. The muscular changes are the same in these cases as are found in the excised muscles. Erb concludes, therefore, that we do not find in the different forms of muscular dystrophy any essential and comprehensive distinction in the histological changes in the muscles, and that these types form one morbid entity—dystrophia muscularis progressiva.

ROYAL COMMISSION ON VACCINATION.

WE understand that the Royal Commission on Vaccination have been considering the terms of an *ad interim* report, which has been drawn up by Lord Herschell. The statements that have been made public as to the supposed tenour of this report are, we are informed, unauthorised and inaccurate.

CRUEL USAGE OF A BRITISH PRACTITIONER IN CHINA.

IT is not often that we have to notice an instance of such wilful, unprovoked, and methodical barbarity as that recorded in the following narrative, which is taken from the letter of an agent of the British and Foreign Bible Society. Dr. Greig, a medical man connected with the Society's mission in North China, while sleeping at an inn was suddenly seized by soldiers, insulted, kicked, and severely beaten. His hands were then tied together behind his back, and he was slung up by them to a beam till he fainted. He was afterwards imprisoned for four days in a miserable hovel, gazed at and abused by the rabble of the place. When at last his release was accomplished at the request of the British Consul he was reduced to a mere wreck of his former self. The alleged reason for this extraordinary treatment is that Dr. Greig was accused, on the evidence of several children, of kidnapping these latter. The charge, which the mere presence of the children must have sufficed to disprove, was of course a baseless one. It is not difficult, indeed, to see that it was a piece of wilful mendacity, probably concocted by some enemy, on purpose to injure an innocent man. Dr. Greig's hard experience does not encourage a belief in Chinese justice. Here we have a man who, as is clearly shown in the letter quoted, has well earned the gratitude and esteem of the Chinese population by his professional skill and kindness. By way of return he is shamefully maltreated on a false accusation of the most trumpery character. It is worth noting also that his chief tormentors were soldiers, and that they are said to have acted under instructions from the local military commandant. These facts, if capable, as we cannot doubt that they are, of legal proof, must reduce considerably the area of responsibility for the abominable treatment he experienced. The onus of blame rests upon official shoulders and the case is evidently one where all possible satisfaction should be exacted by our consular representative.

POLLUTION OF THE THAMES.

IN the annual report of the medical officer of health to the Local Government Board, which has been issued within the last few days, a most important article by Dr. Blaxall on the Sanitary Condition and Administration of the Rural Sanitary District of Staines occupies an important place. In 1887 we published a report by our Sanitary Commissioners on the Thames as a Water-supply for London, and in it we commented somewhat strongly on the sanitary condition of Staines and on the probability that its sewage contaminated the Thames at no great distance above the intake of the water companies near Hampton. Dr. Blaxall has given a much more alarming description of the danger to London from this cause than we ventured upon. Some of our own strong suspicions were suppressed, as we had no wish that injury should be unfairly inflicted upon vested interests. But Dr. Blaxall, armed with the powers of a Government inspector, gives an account of the way in which the cesspools of Staines drain into the river, the sewage sometimes passing down through the foul and porous subsoil as far as Sunbury before it is discharged, which will give unpleasant thoughts to those who still maintain that the Thames between Hampton and Sunbury affords a proper water-supply to London. The subject is too large to be discussed in detail here, but we commend Dr. Blaxall's report earnestly to our readers.

TREPHINING FOR RELIEF OF INTRACRANIAL PRESSURE.

THAT in cases in which an intracranial growth is present much relief is at times given by trephining is now well known, but the number of cases as yet reported is too small to allow of its being recognised as a certain, and at the same time a safe, means of treatment. Such treatment, of course, is only applicable to cases in which either the new growth is too large for removal, or its locality cannot be definitely diagnosed. As regards growths in the cerebellum, clinical observation is still at fault. While in some cases it may enable us to say with a fair amount of definiteness that there is a cerebellar tumour, in very few can it be predicted on which side of the cerebellum the growth lies. Every recorded case, therefore, is of extreme importance, as enabling a judgment to be formed of the difficulties and drawbacks which follow such an operation, as well as of the relief experienced and the nature of the cases in which the operation may be expected to have a favourable result. In the last number of the *Journal of Nervous and Mental Diseases* Dr. Knapp of Boston reports a case in which diagnosis was very difficult, and in which an operation was undertaken chiefly for the purpose of relieving symptoms resulting from increased intracranial pressure. The patient had been fairly well till October, 1889. He then began to suffer from occasional severe headaches, and at times dimness of sight. He was seen at this

Digitized by Google

time to have double optic neuritis. He lost the sense of smell early in the illness, and became totally blind in August, 1890; but on one occasion, after a severe attack of vomiting, he is said to have had a temporary return of vision. He was seen by Dr. Knapp in October, 1890, and then he had for three weeks complained of failure of hearing in the left ear, had experienced some difficulty in swallowing, and there was a profuse flow of saliva. He had also had on two occasions attacks in which he cried out, fell down, and frothed at the mouth. He likewise had sensations of numbness of the face and hands, but tactile sensibility was fairly good. He suffered from headaches, and was restless and slept badly. There was pain on pressure on a spot in the right temple. Sometimes neither knee-jerk could be obtained; at other times only the right was present. Trephining was advised, and was performed on Jan. 18th, 1891. Bone was removed in the right parietal region, just behind the anterior end of the fissure of Sylvius. There was bulging at the opening; but no tumour was felt or seen even after the opening had been considerably enlarged. After the operation he was more comfortable, although not quite free from headache, and at his own request he returned home on Jan. 28th. He returned a few days later, apparently suffering from left hemiplegia and hemianæsthesia, and he remained in a very somnolent condition for some days. There was oozing of blood from the posterior end of the incision, which had apparently broken down, and later on some brain substance came away. On Feb. 14th he became almost comatose, but a profuse watery discharge from the wound set in, and he began to improve. There was no change in the condition of the hemiplegia, or any sign of returning vision, but his mind was much clearer. The hernia, however, continued to slough, and on March 7th he suddenly became worse, and died on the 9th. At the necropsy there were found signs of meningitis around the trephine opening, and a large tubercular tumour in the left lateral lobe of the cerebellum. Of course, in such a case operation was a forlorn hope, for there was little probability that even vision could have been to any extent restored, and it was also a misfortune that breaking down of the scar should have occurred with the consequent hernia cerebri; but the temporary relief from pain, although brief, is significant.

THE PORT OF LONDON.

IN his report to the Port Sanitary Committee of London for the half-year ending December last, Dr. Collingridge lays stress on the need for some amendment of the regulations which allow so small an amount as seventy-two cubic feet per seaman in the mercantile marine. In fact, the whole subject of the existing regulations is carefully discussed so as to indicate the directions in which health requirements demand some modification in the arrangements in force, and the report is especially worthy of study by all who are concerned in port sanitary administration. In considering the various infectious diseases which have had to be dealt with by isolation and disinfection, Dr. Collingridge points out the difficulties in which he is placed with regard to the isolation of small-pox. Admirable as is the port hospital in most respects, the site is, we fear, much too restricted to admit of anything like a small-pox pavilion, except it be constructed so as to consume all out-going air; otherwise patients in other pavilions can hardly fail to run risks to which they should not properly be subjected. Evidently Dr. Collingridge feels this, for he points to the need of either increase of site or selection of a separate one by referring to the vacant land in the possession of the Corporation. The question of the disposal of the metropolitan sewage is rather left in abeyance because the scheme in operation is not completed; but it is alleged that at the present moment, and pending such completion, the state of affairs is unsatisfactory. No less than 7733 vessels were inspected in the half-year, the result being to confer great benefit on seafaring men and a considerable measure of safety from infection to London and the kingdom generally.

IS FARNHAM HEALTHY?

WE should have thought but little of the details of Mr. Sloman's report on the health of Farnham during the past year had it not been for the significant attitude of some members of the local board towards it. Like many other towns, Farnham had an increase in mortality during the influenza epidemic, but there was no special increase of the zymotic rate. The water-supply is not very satisfactory; but amendments are in progress, and some cases of diphtheria were shown to have occurred in connexion with ill-ventilated soil-pipes and other sanitary defects. But it was pleaded at a recent meeting that if the annual report was read in public it must "blacken" the credit of the place, and it is hardly likely that such statements would be made unless the authority knew there were defective conditions the exposure of which they feared. By their attitude they have succeeded in drawing attention to the place, and many will wonder what it is that Farnham is so anxious to hide from the knowledge of the public.

ETIOLOGY OF ACUTE PLEURISY.

IN a paper on the above subject in the *Boston Medical and Surgical Journal* of Feb. 25th, 1892, Dr. G. G. Sears draws attention to the frequency with which phthisis follows an attack of acute pleurisy. He has collected the reports of 451 cases from various observers, of which 176, or 39 per cent., developed phthisis or other well-marked tubercular affection. Constan and Dubrulle, from their army experience, say that soldiers who have suffered from pleurisy are no longer fit for military duty, and that a majority die later of phthisis. An exactly opposite opinion is held by Blachez, who mentions an epidemic of pleurisy which occurred several years ago without the subsequent development of pulmonary disease in a single case. Westbrook, Vickery, and others have reported cases which were followed by phthisis; and from a review of the recent literature there seems to be an increasing tendency to ascribe to the tubercle bacillus a more and more important *rôle* in the causation of pleural effusions; but as the pendulum of medical opinion is proverbial for the length of its vibrations, it is fair to ask if in the present instance it is not tending to swing too far in this direction. The frequent occurrence of pleurisy as a complication of pneumonia, rheumatism, measles, and other infectious diseases where no doubt exists that it is the same in origin, suggests the question if so-called idiopathic pleurisy may not at times be due to the same causes, which for some reason affect only the pleura—a question which the discovery of the pneumococcus in pleural effusions not secondary to pneumonia goes far towards answering, while the reported curative effect of salicylic acid in many cases suggests its being at times a local manifestation of rheumatism. From any series of cases similar to that given above a certain number must be deducted for those who have developed phthisis in the natural order of events without the incidence of a previous pleurisy, while the part which a latent tuberculosis of the bronchial lymph glands may take in the subsequent onset of a more general process must also be considered. In concluding his paper Dr. Sears says that we may consider a very fair proportion of cases of acute apparently idiopathic pleurisy with effusion are followed by phthisis. In some of

Digitized by Google

such cases the pleurisy is doubtless of tubercular origin, and is its earliest expression, just as hæmorrhage may be the first symptom and not the occasion of pulmonary tuberculosis, while of the cases which remain permanently well, in view of the spontaneous recovery of tubercle in other situations, it is fair to assume that a certain number are due to the same cause, the process *remaining* local. In others, though itself benign, pleurisy may be the cause of grave disease, by dislodging the bacilli from their comparatively harmless position in the bronchial glands, or favouring the development of phthisis by crippling the movements of the lung.

THE COST OF POSTAGE OF NOTIFICATIONS.

ON the question of the right of the notifier to send his notifications through the post *unpaid*, or to receive from the sanitary authority the cost of postage, we have received the following opinion, which we are given to understand cannot be disputed. Notifications are not very numerous or bulky, in spite of the loud complaints of a few boards that are surprised at having to pay a medical man for troublesome and responsible duties. They could often be sent by hand :—

"It is not the fact that 'medical men notifying cases are entitled to the full fee without deduction for postage,' for a medical practitioner is not entitled to send his notification by post unpaid, and if he does so the authority is entitled to deduct the surcharge made by the Post Office. This is made quite clear by the Interpretation Act, 1889, Section 26, which provides that when an Act authorises a document to be sent by post, it must be 'properly addressed, *prepaid* and posted.' The Board have frequently pointed out that the Notification Act, in allowing the notification to be sent by post, implies the necessity for prepayment of the postage. The case of Chisholm *v.* Radcliffe Local Board did not raise this question, because the Local Board, despite the advice of the Local Government Board, refused to take in the unpaid notifications, and this they had no right to do. But they might have paid the postage and deducted the money from the fee paid."

THE USE OF ALUMINIUM IN THE MANUFACTURE OF FOOD-CONTAINING VESSELS.

NOW that aluminium is being obtained more cheaply and abundantly from the earths that contain it—clay and cryolite—we may soon expect to meet with a great variety of useful articles made exclusively of this beautiful metal. Aluminium is nearly a third the weight of iron, is both ductile and malleable, and its natural lustre is but little affected by either damp or dry air. The statements, however, that it is not acted upon by even weak acids must, according to recent observations, be received with some amount of reserve. The metal has always been looked upon as possessing properties which would be likely to render it eminently serviceable in the arts and manufactures. Surgical instruments and culinary vessels have already been made of it, and on account of its extreme lightness and portability it has recently been proposed to use this material in the German army for soldiers' mess-tins and water-bottles. In view of this proposal being very generally carried out, several chemists have been led to investigate the action of various liquids and food preparations upon the metal. Some months ago Messrs. Lübbert and Roscher, in a paper on the behaviour of aluminium toward a number of liquids with which that metal might come into contact when made into canteens, cooking vessels, surgical instruments, &c., arrived at conclusions which were considered to be detrimental to the application of aluminium to any use in which it may come into contact with liquids intended to pass into the human body. Professor Lunge, however, was not satisfied with the methods pursued by these investigators, and he accordingly instituted a number of experiments on his own account. The conclusions he came to were as follows: The action of coffee, tea, and beer is *nil* or practically so; *that of brandy is also extremely slight;* the action of acids and acid liquids (wine, sour milk, fruit juices) is more pronounced, but even in this case, he says, far too slight to cause any alarm whatever. Taking the worst case, that of acetic acid, he found a maximum attack of less than five milligrammes per 100 square centimetres in six days, and a canteen holding a litre, and having an inner surface of about 600 square centimetres and an aluminium weight of about 200 grammes, would, he says, in the very worst case lose five milligrammes in a day, or one gramme in 200 days, even if it were always full. At this rate, only in fifty-five years would it be reduced to half its weight. This, he holds, is certainly too trifling an action to be considered; there is not the slightest danger of any injurious action upon the human body by such traces of aluminium compounds, and they are not poisonous, he affirms, in the ordinary sense as compared with compounds of arsenic, mercury, lead, and copper, and, before they can act injuriously, quantities a hundred times larger than those he found to be regularly entering into the human stomach would have to be ingested. Finally, he adds, aluminium may without any fear be employed for canteens or any other vessels used to hold articles of food, at least at ordinary temperatures. These conclusions of Professor Lunge are, however, not by any means confirmed by a report recently to hand through Reuter. It appears that a soldier belonging to an infantry regiment stationed near Nuremburg had his bottle partly filled with cognac. After several sips he was taken ill and vomited. On hearing the particulars the medical attendant decided to send the bottle and its contents to an analyst, who discovered in the bottle some brownish-black spots, round in shape, which under analysis were found to contain large proportions of aluminium and iron. The cognac had become muddy, and the analyst declared that it had caused strong corrosion of the metal. It is quite possible that in this instance the evidently strong action of the cognac on the metal was caused by the presence of the iron, as it is well known that, although the pure metal is frequently unacted upon, yet when it is in contact with another metal galvanic action is oftentimes set up, and consequently corrosion of the metal takes place. The subject is obviously of sufficient importance to demand at once further careful investigation. We should not be at all surprised, however, to learn that aluminium is found to be easily acted upon, seeing how readily it dissolves, with production of hydrogen, both in alkalies and acids. Aluminium is, in fact, one of the three metals of common occurrence which decompose water at a red heat.

OPERATION FOR SPASMODIC TORTICOLLIS.

SOME advance appears to have been made in the surgical treatment of this most distressing affection; but until its pathology is more clearly ascertained, we cannot hope that the results of treatment will be anything like uniformly successful. One point that lies on the surface is the variations met with in different cases. In one patient the sterno-mastoid muscle may be the only one affected, in another it will not be implicated at all, and similar variations are met with in the case of the other muscles which rotate the head. It is, therefore, difficult in some cases to determine exactly what muscles are implicated and to what nerves treatment must be directed. Difficulty also arises from the depth at which some of the muscles and the nerves supplying them are placed, so that any operation on these nerves involves a very deep dissection. Nerve-stretching, even when very thoroughly carried out, has not been attended with success, and simple division of the nerves has not given better results. Surgeons are now dealing with these cases by the free excision of the nerves supplying the affected muscles, removing the nerves as near to their

Digitized by Google

central ends as possible. Last year M. Petit recorded twenty-six cases in which he had excised the spinal accessory nerve. Of these, in thirteen a successful result was obtained, seven were much improved, two were slightly better, and three enjoyed temporary benefit only, while one patient died from phlegmonous erysipelas. The operation in question is a comparatively simple measure. The more difficult cases are those in which the posterior muscles are involved. Early last year Dr. W. W. Keen recorded a case in which he had excised muscular branches of the posterior divisions of the first, second, and third cervical nerves with marked benefit, but not complete success. Soon after Mr. Noble Smith recorded a case in which he had performed the same operation on the second, third, and fourth cervical nerves. Dr. Powers has now related a third instance of this operation, in which he exactly followed Dr. Keen's procedure. The last two patients were greatly benefited by the operation. Dr. Keen makes a transverse incision carried down through the complexus. Mr. Smith employed a vertical incision. The results thus obtained are well worthy of the attention of surgeons, although the treatment is only empirical.

HEALTH OFFICER FOR SUFFOLK.

THE Suffolk County Council are considering the expediency of appointing a county health officer, the question having arisen on the occasion of the receipt of the annual reports of the district medical officers of health. These reports can only be properly examined and dealt with by an expert in public health, and it is noteworthy that the most useful action taken by county councils, by way of bringing local default to the fore and of securing amendment in sanitary administration, has been effected by councils which have elected their own health officers instead of paying a fee to a mere examiner of reports, whose duties end when he has sent in his summary, together with such advice as he may see fit to tender.

CHEAPER TRAVELLING TO THE CONTINENT.

PATIENTS wintering on the Riviera will realise considerable economy in their travelling expenses if they defer their return till after April 1st. The French railway companies pay a tax of 12½ per cent. to the Government on passenger and parcel traffic, on dogs, &c. But, after the war, on Sept. 17th, 1871, a war tax of 10 per cent. extra was imposed. Thus, for nearly twenty-one years the railway companies have had to give 22½ per cent. of their receipts to the Government. The time has at last arrived, however, when the Government can afford to dispense with the war tax; but, before making this remission of taxation, the railway companies were called upon to make similar concessions. It was pointed out that national welfare depended to a great extent on facilities for travelling, and both the companies and the Government adopted this broad view of the subject. Consequently, on and after April 1st a reduction will be made on all French railways which will be equal to 10 per cent. on all first-class single tickets; of 18 per cent. on all second-class single tickets, and of 27 per cent. on all third-class single tickets. It is, however, on return tickets that the first- and second-class travellers will derive the greatest benefits, for these are to be reduced 25 per cent. The third-class return tickets will only be lowered 20 per cent.; but it must be borne in mind that return tickets were already sold at a reduction. As a practical illustration of this new tariff, the first-class return ticket from London to Nice, available for forty-five days, will cost £10 8*s.* 6*d.*, instead of, as at present, £13. Again, the first-class return ticket from Victoria to Paris and back will be £4 6*s* 9*d.*, instead of, as at present, £4 18*s.* 3*d*; and the second-class return will be £3 6*s.* 3*d.*, instead of £3 18*s.* 3*d.* The greatest advantage will be reserved for the third-class travellers. The cheap and slow night service available for fourteen days only is to be abolished, and in its stead a great reduction will be effected in the charge for the third-class which has quite recently been added to the night mail. The third-class night mail return ticket from Victoria to Paris, which now costs £2 13*s.* 2*d.*, will be issued for £2. The Chatham and Dover line also proposed to give £2 return third-class tickets by the morning mail, which starts at 8.30 A.M., and reaches Paris at 5 50 P.M., but the proposition met with some opposition. The directors were, however, able to secure the issuing of such tickets at least during the tourist season; so that in the summer it will be possible to go, third-class return, to Paris for one month by the shortest sea route and by day for £2. We need scarcely insist upon the advantage of these reductions. If they only affected pleasure-seekers we should not be so much concerned, but we are daily learning to recognise how great are the benefits to health to be derived from a change of climate, scenery, and surrounding circumstances. The cost of travelling is, however, a great obstacle, particularly as invalids ought not to travel alone. Where, as is often the case, a family party determine to winter in the South because one among them is in a state of delicate health, the expense of the journey thus multiplied by the number of the party becomes a very serious consideration. On the other hand, if the patient goes alone, the solitude, the sense of being exiled from friends and home, may do more injury than the change of climate does good. There is no doubt, therefore, that lessening the cost of travelling will be an indirect adjuvant in the climatic treatment of disease.

THE DRAINAGE OF WOKING.

THE prospective drainage of the district about Woking railway station has now entered on a second stage. One site for the disposal of the sewage was refused by the Local Government Board last year, great local opposition having been raised to it. Now another site has been selected, and application for a formal inquiry as to its acquisition will probably be made. We move but slowly in such matters, and local opponents often find but little difficulty in causing needless delays. Any such delays should, if possible, be avoided in this case, for the large population now pouring all its liquid filth into cesspools in close proximity to dwellings in this locality can hardly fail to suffer if the present state of affairs is continued much longer.

UNQUALIFIED PRACTICE, "COVERING," AND "FALSE CERTIFICATE" OF DEATH.

AN inquest was held on the 22nd inst., at the Coroner's Court, chapel of ease grounds, by Dr. Danford Thomas, on the body of Susannah Elizabeth Waller, aged seven months. The inquiry was held in consequence of the certificate of death being signed, and apparently filled up, by a qualified medical man, he not having seen the case either before or after the death had taken place. It appeared from the evidence of the parents, living in Palmerston-road, Holloway, both respectable people, to whom no blame could possibly be attached, that, the child being taken ill about three weeks since, the father went off in search of a medical man, and calling at a "dispensary" near to his house in Poole's Park, N., went in and asked to see the doctor. A gentleman appeared, accepted the message, and called later, seeing the child and prescribing for her, and gave medical directions as to treatment. The parents were under the impression they were dealing with a properly qualified medical man, and permitted the attendance to continue until the child's death on the 18th inst. On asking for a certificate the "doctor"

Digitized by Google

stated that he would send one in, and did so, the certificate being signed by Mr. Dyte. As the parents did not know the name of the person who had attended during the illness all would probably have gone off well had it not been for a neighbour, who, believing that the child had been treated by an unqualified practitioner, requested her own medical man to call at the house. On arriving there he found that the child was dead. Certain inquiries were then instituted, which resulted in the district registrar refusing the certificate which had been brought to him, and referring the matter to the coroner. Mr. Smyth, the person who took charge of the child and attended it medically, was called into court, and gave evidence that Mr. Dyte had never seen the child alive, that the certificate was signed by him (Mr. Dyte), and that he (Mr. Smyth) had been his assistant for fifteen years, and that he was unqualified. The parents also identified Mr. Smyth as the man to whom they, thinking he was a "real doctor," had entrusted the case, and swore that they had never seen or heard of Mr. Dyte, and that no other person than Mr. Smyth had attended the case. There was no dispute as to the facts adduced above. Mr. Dyte was not present, although the coroner pointed out that he had received notice that an inquiry would be held. After the coroner had pointed out the grave nature of the case, the jury returned a verdict of "Death from natural causes," and added a rider "that the attention of the Registrar-General be called to the case, as a false certificate had without doubt been issued."

EMIGRATION OF LEUCOCYTES FROM THE TONSILS.

DR. POLYAK finds that most of the leucocytes which in a normal condition of the tonsil migrate through its epithelium into the buccal cavity are lymphatic corpuscles (lymphocytes)—that is to say, young elements generated by karyokinesis of the cells of the adenoid tissue. There are, however, in addition, a considerable number of leucocytes with polymorphic nuclei which migrate from the superficial capillaries and capillary veins. The emigration of these multi-nuclear leucocytes is also observed in places where there is fibrous connective tissue beneath the epithelium. The emigration of large numbers of lymphocytes is accompanied by well-marked destruction of epithelium close to the free surface, but the emigration of the multi-nuclear leucocytes only appears to give rise to increased exfoliation of the superficial epithelial cells. When acute inflammation of the mucous membrane was induced by irritation with chemicals, the emigration through the many layers of flattened epithelium was mainly confined to multi-nuclear leucocytes.

LEEDS INFIRMARY EXTENSION.

THE new buildings added to the Leeds Infirmary, which have been constructed at an outlay of £35,000, are now completed. They comprise four separate blocks—namely, (1) ward pavilion, (2) out-patients' department, (3) pathological department, and (4) isolation wards. These form a very handsome and much needed addition to the infirmary, which already held a high place amongst buildings of its class. We note, however, that some discussion has taken place in the local press regarding the allocation of the new wards in the first-named block. These wards, of which there are two on each of the three floors, one containing ten beds and the other sixteen beds, are divided by the staircase and corridor, in which is placed a small special ward and the nurse's room. The main wards are thus assigned: on the ground floor they are both given up to ophthalmic and aural cases; on the first floor, the smaller ward is devoted to the same class, and the larger to the gynæcological cases; whilst on the third floor, where the arched roof adds some feet to the height of each ward, the larger is devoted to diseases of children (medical), and the smaller to cases of burns, gangrene, &c., which it is thus intended to draft off from the general surgical ward. It is this latter plan to which objection has been taken, and with some force, for, although the ward in question is on the top floor, the class of cases intended to be lodged in it are peculiarly offensive, and the near proximity of the gynæcological ward, where operation cases of a grave nature are likely to be found, makes the alteration one which cannot be commended. It seems a pity that, with the resources at the command of the authorities, some more fitting plan for the isolation of these cases, which ought to be separated from general surgical cases, could not have been devised than one which may entail risk to the safety of other patients contained in the same block.

SMALL-POX AND FOOTBALL.

A GOOD deal of ill-feeling has been created in the urban districts round about Dewsbury, and within the Dewsbury Union, because certain football clubs have refused to go to such places as Batley, Heckmondwike, and Dewsbury to play matches. We have no hesitation in saying that the refusals have been most proper; and we would further add that a certificate, published by the Batley inspector of nuisances, to the effect that Batley may be visited "without any danger," is perfectly worthless in the face of the well-known story of Batley's long-maintained prevalence of small-pox. Football players have generally reached an age when the protection of primary infantile vaccination is wearing off, and very recent revaccination is not the best preliminary to the physical struggles which are involved in a football contest. Persons desirous of visiting any of these Dewsbury towns, which have been, and still are, infected with small-pox, had better avoid all large assemblies there until the medical officers of health have certified that the risk is past, and this is hardly likely to be so until we have something better to record than a persistent attitude of opposition to vaccination (a prophylactic which could bring the epidemic to a speedy end), a hurried concentration of small-pox patients in local hospitals, and the existence of some eighty fresh cases this year in a single one of these towns, the heaviest incidence of all being during the last fortnight of February and the beginning of March.

INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THE members of the recent Congress are entitled to receive, free of charge, the whole of the Transactions. The whole of the thirteen volumes cannot be ready for some months. The records of certain sections are, however, now nearly ready, and can be obtained by members, if desired, as soon as issued by forwarding to the publishers, Messrs. Eyre and Spottiswoode, the sum of 4*d.* per part, or 4*s.* for the whole series, to cover the necessary expense of wrapping and postage. A further sum of 9*d.* must be remitted if the member wishes to receive the Transactions bound in cloth. To non-members a single copy will be sent on payment of 2*s.* 6*d.* (or 2*s.* 10*d.* post free), or the whole series of thirteen volumes will be forwarded for £1 16*s.* 6*d.*, post free. The copies can also be obtained bound in cloth at a charge of 4*s.*, post free.

THE HEALTH OFFICER FOR SOUTHWARK.

WE have noticed with considerable regret the attitude which has been adopted by the Vestry of St. George-the-Martyr, Southwark, towards Dr. Waterworth, who for many years has acted as medical officer of health for the district. He voluntarily resigned his post a short time ago

Digitized by Google

in order to enable the vestry to re elect him, so that the new appointment might carry with it repayment of a moiety of the salary by the County Council. Some irregularity having occurred in the terms of the new appointment it was not sanctioned, and now some members of the vestry, availing themselves of the fact that there is technically a vacancy, have induced their colleagues to advertise for an officer to give his whole time to the duties for £500 a year. We do not discuss the sanitary wants of Southwark in connexion with such whole-time service, but it will be well for intending candidates to ascertain the details which have led up to this extraordinary behaviour towards Dr. Waterworth—behaviour which, at the vestry meeting itself, was described by one of its members as "disgraceful."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. B. Küssner, Extraordinary Professor of Medicine in the University of Halle.—Dr. Karavaeff, Emeritus Professor of Surgery in the University of Kieff.

THE Ingleby Lectures will be delivered by Dr. Arthur Foxwell, in the Medicine Theatre of Queen's College, Birmingham, on March 29th and April 5th and 12th, at 4 P.M. The subject will be "The Condition and Treatment of the Vascular System in Chlorosis and other Debilitated States."

ACCORDING to the special correspondent of *The Times*, upwards of 200 ocean vessels have been infected with yellow fever, including those in the ports of Brazil, whose crews are either dead or have fled.

THE Local Government Board have finally agreed to the pension of £210 to Dr. Collie, who recently resigned his appointment as medical superintendent of the Eastern Fever Hospital.

DR. THOMAS CLIFFORD ALLBUTT, F.R.S., Regius Professor of Physic in the University of Cambridge, has been elected to a Fellowship at Gonville and Caius College.
